EXOPOLYSACCHARIDES FROM *LACTOBACILLUS*: BIOSYNTHESIS, CHARACTERIZATION, FUNCTIONAL ASPECTS AND APPLICATIONS IN FOOD INDUSTRY

Elisa C. Ale, Jorge A. Reinheimer and Ana G. Binetti*

Instituto de Lactología Industrial (INLAIN; UNL-CONICET),
Santa Fe, Argentina

ABSTRACT

Exopolysaccharides (EPS) are high molecular weight biopolymers produced by a wide range of microorganisms, including lactic acid bacteria (LAB). These polymers can be secreted to the external environment (slime EPS) or adhered to the cell bacterial surface (CPS). Once they are released to the medium, they are able to change its rheology, property that was frequently used by the food industry. Likewise, EPS have been associated with beneficial health effects, making them attractive molecules to be applied as food ingredients.

Lactobacillus is a wide genus of LAB including more than 200 species which has been of great interest because strains with technological, as well as functional (probiotic) properties were described. The present chapter reviews the current knowledge about the role of EPS production in lactobacilli strains, as well the aspects regarding biosynthesis, chemical structure, screening and quantification methods, focusing on the impact of their chemical structure and composition on the possible health benefits and their technological application in novel food products.

INTRODUCTION

Some lactic acid bacteria (LAB) are able to produce exocellular polymers or exopolysaccharides (EPS) which can be secreted to the medium (slime EPS) or remained attached to the cell wall (capsular polysaccharides or CPS). These molecules are frequently

* Corresponding Author's Email: anabinetti@fiq.unl.edu.ar.

used by the food industry, for example by the application of EPS-producing strains in the manufacture of fermented milk and different types of cheese, improving their textural and organoleptic properties. Furthermore, some EPS are able to reduce syneresis in yogurts due to their water-retention properties and, besides, they can be used as fat replacers in low-fat dairy products, allowing the design of healthy products with acceptable sensory characteristics. Furthermore, EPS were associated with positive health effects, among these are their bifidogenic/prebiotic role, stomach ulcer protection, cholesterol-lowering and immunomodulatory properties. It has also been described that EPS provide protection against different pathogens (virus and bacteria) and present antioxidant and antitumor effects.

Particularly for LAB, the ecological or physiological role of EPS for the producing bacterium remains unclear, and has been associated with a protective role in various niches (biofilm formation) and with carbon catabolism (Schwab et al., 2007; Zannini et al., 2016). In general, it is believed that EPS are not used as an energy source by the producer strain, but there might be some exceptions (Baruah et al., 2018). In some cases, the presence of CPS may protect the producing cell by preventing phagocytosis (Tahoun et al., 2017; Meijerink et al., 2012). A possible hypothesis indicates that some protective roles of these molecules can be associated to the adaptation of the producing bacteria to the stressful conditions of their natural ecosystems such as the gastrointestinal tract and fermented foods (Ruas-Madiedo et al., 2008). EPS have been associated with both rheological and functional effects on the matrix where they are added or synthesized, but the final response strongly depends on their chemical structure and the way of interaction with the medium components. Among LAB, *Lactobacillus* is a wide genus including more than 200 species (Salveti et al., 2018) which has been of great interest because strains with technological, as well as functional (probiotic) properties were described, frequently associated to the synthesis of EPS.

The aim of this chapter is to review the current state of the art about the chemical structure and genetic organization of EPS in the *Lactobacillus* genus, the methods for EPS isolation and optimization, the potential benefits on human health and the technological applications for the design of novel techno-functional foods, focusing on the structure-function correlation.

CLASSIFICATION, BIOSYNTHESIS AND GENETIC ORGANIZATION

Bacterial EPS are carbohydrate polymers which generally present glucose, fructose, galactose, rhamnose and fucose in their structure (Ruas-Madiedo et al., 2002). In some cases, the presence of different isomers, linkage types and organic and inorganic monosaccharide substituents could be found as well. The oligosaccharide repeating units can present different degrees of polymerisation and branching patterns and are responsible for the great diversity among lactobacilli EPS.

These relatively long-chain and high-molecular-mass polymers can be classified into two main groups: they can be composed of only one type of monosaccharide (homopolysaccharides, HoPS), or can present more than one type of monosaccharide in their structure (heteropolysaccharides, HePS); the mechanisms of biosynthesis are different between them (Cerning, 1990; 1995). HoPS are formed by the action of enzymes called glucansucrases (or glucosyltransferases, GTF) and fructansucrases (or fructosyltransferases,

FTF), depending on the composition of the polysaccharide in formation (glucans and fructans, composed exclusively by glucose or fructose, respectively). Both enzymes are glucoside hydrolases that catalyze transglycosylation reactions in the extracellular environment, using sucrose as substrate and obtaining the necessary energy from the molecule breakdown (Figure 1A). The structures of these enzymes are very different, glucansucrases have numerous domains that belong exclusively to LAB, and synthesize α -glucans that differ in their type of glycosidic bounds, degree and type of branches, molecular mass and solubility. On the other hand, fructansucrases are present in Gram positive and Gram negative bacteria, and synthesize β -fructans with $\beta(2,6)$ (inulin) or $\beta(2,1)$ linkages (levan) (Hijum et al., 2006). HoPS can be classified in four subgroups according to the monomers and linkages involved: α -D-glucans (dextrans), β -D-glucans, β -fructans (such as levan and inulin), and others like polygalactans. They are produced by several LAB genera, including *Lactobacillus*, *Streptococcus*, *Leuconostoc*, *Oenococcus*, and *Weissella* (Dimopoulou et al., 2017; Hijum et al., 2006). Thus, due to the great diversity of species that form part of the *Lactobacillus* genus, the EPS synthesized by them seem to be very attractive molecules for numerous novel applications. In the case of β -glucans, only one gene is required for their biosynthesis, which encodes a β -glycosyltransferase, a membrane protein whose topological prediction indicates that β -glucan, or at least its repeating unit precursors, are synthesized in the cytosol (Werning et al., 2006; Werning et al., 2012). Besides, *in vitro* recent experiments indicate that the β -glucan is synthesized directly from activated UDP-glucose (Fraunhofer et al., 2018; Werning et al., 2008), similarly to HePS. This could explain the production of a β -glucan with only glucose as the C source for *Lactobacillus (Lb.) fermentum* Lf2 (a widely studied strain from our group), and not sucrose, as it would be expected for HoPS (Ale 2018; Vitlic et al., 2018). Werning et al., (2012) suggested that the association of several GTF monomers could form a pore for extrusion of the EPS. However, other alternative mechanisms might allow the translocation or secretion of β -glucans across LAB membranes, such as those mediated by ABC-like transporters, related to the export of various bacterial polysaccharides (Silver et al., 2001). In the presence of certain sugar acceptors (like maltose), glycansucrases can form low-molecular-mass oligosaccharides from sucrose (Korakli & Vogel, 2006). Their synthesis occurs via successive transfer of glucosyl or fructosyl units to the acceptor rather than the glucan or fructan polymer, with the consequent formation of glucooligosaccharides (GOS) or fructooligosaccharides (FOS), respectively (Lynch et al., 2018).

On the other hand, HePS are molecules composed by repetitive units which present mainly D-glucose, D-galactose and L-rhamnose, and are formed by 2 to 8 monomers. Other monosaccharides, such as fructose, fucose, mannose, N-acetylglucosides, and glucuronic acid, as well as noncarbohydrate moieties (phosphate or acetyl groups) can be present as well (De Vuyst & Degeest, 1999a; Werning et al., 2012), conferring them particular characteristics. HePS are produced by the polymerization of sugar-nucleotide precursors (e.g., UDP-glucose and UDP-galactose) provided by the cell, and the biosynthesis is controlled by several glycosyltransferase genes that are involved in the regulation, chain-length determination, polymerization and export of the repeating units. These genes are generally located together in an operon and constitute an EPS biosynthesis cluster (Werning et al., 2012). All the details of the mechanism are not yet fully understood, but a flippase enzyme may be involved in the transfer of the lipid-bound polymer to the external side of the membrane, where the polymerization of the repeating units takes place (Lebeer et al., 2009). Figure 1B shows the main steps for the synthesis of HePS in LAB. Briefly, activated sugar

nucleotides bind to a phosphorylated lipid carrier (such as C55- polyprenyl phosphate) located on the cytoplasmic side of the cell wall by the enzymatic activity of a priming glycosyltransferase associated to the membrane. After this, a series of additional glycosyltransferases catalyze the synthesis of the repetitive unit of the EPS, which is then transported to the outer surface of the bacterial membrane by a flippase (Flippase-like Transmembrane Lipid Transporter, FTLT, also identified as Wzx/Wzy-dependent pathway, according to the nomenclature described for *Escherichi (E.). coli*; Schmid 2018). Once it is outside, the repetitive units are polymerized and the chain length seems to be regulated by a phosphatase that hydrolyzes the lipid diphosphate anchor of the membrane. These genetic clusters are located mainly in the bacterial chromosome, as it was described for *Streptococcus (Strep.) thermophilus*, *Lb. plantarum* or *Lb. fermentum* (De Vuyst & Degeest, 1999b; Siezen et al., 2010; Stingelet al., 1996; Dan et al., 2009). As it was mentioned above, the genes involved in the HePS synthesis are usually located in operons, with all of them oriented in the same direction, allowing the transcription of a single mRNA molecule (Jolly & Stingelet, 2001; Lebeer, Vanderleyden & Keersmaecker, 2008) and are highly conserved among lactobacilli (Lebeer, Vanderleyden & Keersmaecker, 2008). Until now, the genes involved in the regulation of HePS synthesis were detected in lactobacilli but not in bifidobacterial *eps* clusters (Jiang and Yang 2018). A conserved “consensus” *eps* cluster structure for *Lactobacillus* (among other LAB) was proposed starting (from 5’ to 3’) with genes responsible for the transcriptional regulation and chain-length determination, followed by a core of GTF and ending with genes for polymerisation/export, all flanked by transposases (and derivatives) or insertion sequences (Figure 2) (Castro Bravo et al., 2018).

A typical characteristic found in *eps* clusters is the presence of mobile genetic elements in the DNA region involved in HePS or HoPS synthesis (Péant et al., 2005; Tiekings et al., 2005; Hijum 2004). These elements allow horizontal transfer between different genera and their presence could justify the instability of the HePS- producer phenotype of some strains (Ruas-Madiedo et al., 2009). The *gtf* genes (coding for β -glycosyltransferases) of LAB are usually flanked by genes which could be involved in functions of conjugation and recombination. Thus, horizontal transfer mediated by plasmids, or transposition events, might explain the wide distribution and high degree of *gtf* gene preservation in β - glucan-producing strains along different genera (Werning et al., 2006).

METHODS FOR ISOLATION AND PURIFICATION OF EPS AND CPS

The total yield of EPS produced by the LAB strongly depends on the composition of the medium (C and N sources) and the conditions in which the strains develop, such as temperature, pH, oxygen tension, and incubation time (Degeest, Vaningelgem & De Vuyst; 2001). It has been described that the adjustment of the fermentation conditions can lead to higher EPS levels (Ale et al., 2016b; Zisu & Shah, 2003; Petry et al., 2000). For example, temperature modifications presented varying effects on EPS production (De Vuyst & Degeest, 1999b). It has been shown that lower temperatures are better for HoPS synthesis, as glycanucrases have a lower optimum temperature range (Kang, Oh & Kim, 2009). In a recent study by our group, the statistical optimization of the EPS production by *Lb. fermentum* Lf2 was achieved, doubling the yield obtained under non-optimized conditions

(1 to 2 g/L, approximately). In this case, sucrose was more effective than glucose as the C source, and the proportions of the three nitrogen sources of the semidefined medium applied were critical (SDM, Kimmel & Roberts, 1998), as well as the pH and time of fermentation (Ale, 2018).

Figure 1. EPS-biosynthesis pathways proposed for homopolysaccharides (HoPS, A) and heteropolysaccharides (HePS, B).

Figure 2. Organization described for the HePS gene clusters.

When quantification of the EPS yield is approached, it is important to highlight that the presence of glucomannans (originating from yeast extract and peptone, both included in general media for lactobacilli, like MRS) can co-precipitate with EPS. For this reason, the use of semi-defined media for EPS quantification and purification is recommended (Ruas-Madiedo & de los Reyes-Gavilán, 2005).

In general, the molecular mass of HoPS is greater than 10^3 kDa (Ruas-Madiedo et al., 2009) and are produced in amounts higher than HePS, in the range of g/L, reaching values of up to 10 g/L (Lynch et al., 2018). HePS are synthesized in low amounts, in the range of mg/L, and their molecular mass ranges from 40 to 9×10^3 kDa (Ruas-Madiedo et al., 2009).

Several screening strategies have been applied to detect EPS-producing bacteria. For example, Vedomuthu & Neville (1986) used 1.0 mL pipettes to test the ropiness of acidified reconstituted skimmed milk, assessing mucoidness by the stringiness of the free flowing gel. This method was also described by Mozzi, Torino & de Valdez (2004), defining ropy as strings longer than 6 mm. A variant to the ropy-screen method employs an inoculation wire loop to assess string formation upon touching a colony. In this case, when the string was longer than 5 mm, the strain was considered ropy (Dierksen, Sandine & Trempey, 1997). Although these techniques are easy to perform, they are difficult to standardize since the results obtained are qualitative rather than quantitative. A screening approach using microhaematocrit capillaries to measure efflux, a parameter that correlates with viscosity measurements was also described (Ricciardi, Parente & Clementi, 1997). In general, visualization of slimy or mucoid colonies on solidified media is probably the most frequently used screening method for EPS production, with the disadvantage of only detecting strains with an evident ropy phenotype.

Staining methods are also used for detecting EPS-producing cells, for example by the use of ruthenium red, neutral red, calcofluor white, congo red or Indian ink. Ruthenium red was used to detect *Strep. thermophilus* mutants with loss of ropy phenotype, which appeared as red colonies on milk agar media, while ropy wild-type strains appeared white (Stingele et al., 1996). Although staining assays are relatively easy to perform, the visual interpretation can be difficult when small differences between positive and negative signals occur (Zeidan et al., 2017).

All the screening approaches mentioned above rely on the presence of a physical change in the environment that can be observed by visual inspection. A more direct approach involves gravimetric quantification of the EPS produced. Depending on the medium, certain pre-treatment steps are required in order to obtain the EPS extract with the minor interferences as possible. For example, heating steps are used to inactivate endogenous enzymes that could degrade the polysaccharides (Shao et al., 2014). In general, for broths like MRS, centrifugation is typically carried out to separate the cells, and then the EPS are precipitated from the supernatant with chilled absolute ethanol (Juvonen et al., 2015; Dilna et

al., 2015; Hermann, Petermeier & Vogel, 2015; Zarour et al., 2017). Briefly, the protocol applied could be summarized as follows: (i) cell removal by centrifugation or filtration; (ii) EPS precipitation from the supernatant by the addition of chilled absolute ethanol or acetone (2-3 volumes); (iii) dialysis to remove low molecular mass contaminants (12-14 kDa cut off); and (iv) freeze-drying of the precipitated polysaccharide. In some cases, a second precipitation and dialysis step is carried out (Torino, de Valdez & Mozzi, 2015; Ruas-Madiedo & de los Reyes-Gavilán, 2005). Polak-Berecka et al., (2013) found that a heat treatment at first step is critical to inactivate EPS or CPS-degrading enzymes. Besides, they do not recommend too high centrifugal rates ($> 10,000$ g) to discard the cell pellet, since part of the EPS could be eliminated as well.

Further purification could include more sophisticated steps such as membrane-filtration, anion-exchange and/or gel permeation chromatography (Leivers et al., 2011; Sanz & Martínez-Castro, 2007; Shao et al., 2015).

The quantification of EPS yield may be gravimetric (expressing the yield as mg/L) or colorimetric, by the phenol-sulphuric acid method (Dubois et al., 1956). In this last case, simple sugars, oligosaccharides, polysaccharides and their derivatives (including the methyl ethers) give an orange-yellow colour when they are treated with phenol and sulphuric acid.

When the EPS is isolated from high protein content media, such as dairy products, proteins are usually precipitated with trichloroacetic (TCA) acid, or removed by hydrolysis with proteases or by a combination of both (Torino, de Valdez & Mozzi, 2015), followed by the alcohol precipitation, dialysis and freeze-drying steps.

Regarding CPS, they can be visualized by microscopy after negative staining with Indian ink (Mozzi et al., 1995), a technique that evidences a bright white layer surrounding the cells when CPS are present. For the same purpose, Malang et al., (2015) used crystal violet to stain the cells blue to facilitate the differentiation of CPS in the dark background. To isolate the CPS, the cell pellet can be washed with PBS buffer and, after resuspending the cells in NaCl (1 M), a sonication step is applied to detach the CPS from the cells. Then samples are centrifuged to eliminate insoluble material and the supernatant is precipitated with chilled ethanol as described previously for EPS (Fraunhofer et al., 2018; Tallon, Bressollier & Urdaci, 2003; Toba, Kotani & Adachi, 1991). An alternative method with ethylenediamine tetraacetic acid (EDTA) has also been described (Tallon, Bressollier & Urdaci, 2003); in this case, the cell pellets are resuspended in 0.05 M EDTA. Then, the mixture is incubated under gentle agitation for 4 h at 4 °C and centrifuged and a precipitation step with ethanol is done as described above. The efficiency of this last technique will depend on the nature of the bonds between CPS and the cell wall. In another work (Mende et al., 2013), CPS were detached from the harvested cells suspended in water by applying a heating step (90 °C, 15 min), cells were then removed by centrifugation and the detached CPS was isolated from the supernatant.

CHEMICAL AND STRUCTURAL CHARACTERIZATION OF EPS

In relation to the chemical characterization of EPS, the polymer molecular weight (MW) can be measured by HPSEC-RI (High Performance Size Exclusion Chromatography-Refractive Index) and an increased use of SEC-MALLS (Size Exclusion Chromatography - Multi-Angle Laser Light Scattering) was observed lately (Picton, Bataille & Muller, 2000;

Leivers et al., 2011; Patten et al., 2014). There are other complex techniques that can also be used to determine the average MW, such as Field Flow Fractionation (FFF) and Hydrodynamic Chromatography (HDC) (Isenberg et al., 2010; Galle et al., 2011).

Table 1. Lactobacilli EPS-producing strains, chemical characteristics and potential applications

Strain	EPS	Application	Reference
<i>Lb. sanfranciscensis</i> LTH2590 (= TMW 1.392)	β (2,6) levan	Improvement of bread texture and dough rheology	Brandt et al., 2003
<i>Lb. buchneri</i> FUA3154	Galactose, glucose, one unidentified; MW $10\text{-}10^2$ kDa	Wheat and sorghum sourdough rheology	Galle et al., 2011
<i>Lb. plantarum</i> BR2	Glucomannan; MW 2.38×10^3 kDa	Antioxidant and lowering cholesterol activities, antidiabetic potential	Sasikumar et al., 2017
<i>Lb. kefiranofaciens</i> 1P3 <i>Lb. satsumensis</i> 10P and 10P2	Glucans, most of the residues linked by α -(1,6) glycosidic bonds (~90%); estimated MW 8×10^2 kDa	Increase in IgA ⁺ B cells, suitable for food ingredient	Paiva et al., 2016
<i>Lb. paracasei</i> CIDCA 83123 <i>Lb. paracasei</i> CIDCA 8339 <i>Lb. paracasei</i> CIDCA 83120 <i>Lb. paracasei</i> CIDCA 83121 <i>Lb. paracasei</i> CIDCA 83124	Main component: a fraction of MW $10\text{-}10^2$ kDa, but a high MW fraction was also observed: EPS produced by <i>Lb. paracasei</i> CIDCA 8339 and <i>Lb. paracasei</i> CIDCA 83124 had a MW fraction of 10^2 Da– 10^3 kDa. EPS produced by <i>Lb. paracasei</i> CIDCA 83120, <i>Lb. paracasei</i> CIDCA 83121 and <i>Lb. paracasei</i> CIDCA 83123 had a fraction with MW $> 10^3$ kDa	Interesting rheological properties in fermented milk, which would be useful for food application	Hamet, Piermaria & Abraham, 2015
<i>Lb. mucosae</i> DPC 6426	Mannosyl residues, with mannose, glucose and galactose found to be the major sugar residues present in an approximate ratio of 3:2:2	Decrease in syneresis in low-fat yogurt and viscosity increased for the EPS-rich yogurts; improved sensory properties of Swiss-type cheese	London et al., 2014 ; 2015; Ryan et al., 2015
<i>Lb. fermentum</i> Lf2	Glucose and galactose 2:1, composed of a high MW fraction ($> 1 \times 10^3$ kDa) and a low MW fraction (90 kDa)	Increase of the hardness and consistency index of low-fat yogurts, with no sensory defects	Ale et al., 2016b; Vitlic et al., 2018
<i>Lb. suebicus</i> CUPV225 <i>Lb. suebicus</i> CUPV226	Glucose, galactose, N-acetylglucosamine and phosphate (in different ratios), mixture of polysaccharides; two fractions: 2×10^4 and $1.5\text{-}7.8 \times 10^6$ g/mol, depending on the C source	Potential immunological and technological properties	Ibarburu et al., 2015
<i>Lb. paracasei</i> 20408	EPS with unknown structure	EPS ⁺ mutant showed a positive impact on the textural, melt, proteolysis, and sensory characteristics of half-fat Cheddar cheese, useful as fat replacer	Zhang et al., 2015

The EPS monomer composition can be determined by total acid hydrolysis (sulphuric or trifluoroacetic acid at 120 °C) followed by detection using high performance anion exchange chromatography (Ale et al., 2016b; Fraunhofer et al., 2018). Additional information about the

structural characteristics can be studied by ^1H and ^{13}C NMR spectroscopy (Leivers et al., 2011; Balzaretti et al., 2017). This method provides information of the type of monosaccharides, ring size, anomeric configuration and positions of the glycosidic linkages (Torino, de Valdez and Mozzi 2015). In fact, more than fifty different NMR-EPS repeating unit structures have been described for lactobacilli and bifidobacteria (Castro-Bravo et al., 2018), representing in some cases unique structures (Ruas-Madiedo, 2005). In Table 1, some characteristics of EPS from lactobacilli were summarized, together with their potential food applications. For example, in a recent study of our group (Ale, 2018; Vitlic et al., 2018), the structure of two EPS produced by *L. fermentum* Lf2 was elucidated by NMR. The two EPS were separated by preparative size exclusion chromatography to give a high molecular mass β -glucan (1.23×10^3 kDa) and a medium molecular mass heteroglycan (88 kDa), the last composed of glucose and galactose. Their structures were determined using a combination of NMR spectroscopy, monomer and linkage analysis.

Recently, a high-throughput screening method was described for the determination of EPS concentration and monosaccharide composition (Rühmann, Schmid, and Sieber 2016). The method consists of the following steps: cultivation, cell removal by centrifugation and filtration, sugar monomer removal by gel filtration, EPS hydrolysis with trifluoroacetic acid and derivatization with 1-phenyl-3-methyl-5-pyrazolone (PMP) and monomer detection by UHPLC-UV-ESI-MS (Ultra High Performance Liquid Chromatography with Ultra Violet and Electrospray Ionization Ion Trap Mass Spectrometer).

Molecular screening approaches have also been applied to the search for new EPS-producing isolates. The strategy comprises the design of degenerate primers based on LAB gene sequences followed by PCR reaction and sequencing of PCR products. This approach has been mainly applied to identify glucan and fructan-producing strains (Krajl et al., 2003; Malik et al., 2009). With genome sequencing, it is currently easier to study EPS-related gene sequences and the structure of the clusters involved in EPS synthesis. However, this technique is not suitable for arising to conclusions regarding yield and type of polysaccharides, or even rheological properties when applied in different food matrices.

POTENTIAL APPLICATIONS OF EPS FROM THE GENUS *LACTOBACILLUS* IN THE FOOD INDUSTRY

EPS are attractive molecules with great potential to be used as ingredients in food matrices since they are natural and safe components when they are produced by GRAS (General Recognized as Safe) microorganisms, such as lactobacilli. Although they have low yields, their production *in situ* is suggested as an option for the food industry, for example by the application of EPS producing adjunct or starter cultures (Hassan, Awad & Muthukumarappan, 2005; Ryan et al., 2015; Han et al., 2016; Amatayakul, Sherkat & Shah, 2006b; Hassan et al., 2003; Yilmaz et al., 2015). EPS, mainly HePS, have been widely used in the dairy industry, since they are able to improve certain attributes due to their thickening properties. Besides, they have been related to syneresis reduction and firmness increase (Ale, et al., 2016b; Dabour et al., 2006; Zisu & Shah, 2005).

For the design of novel foods with improved technological and functional characteristics, it is crucial to find new EPS-producing strains able to impart the expected characteristics to a

specific food matrix. In this sense, an important number of EPS-producing *Lactobacillus* was isolated from diverse food matrices, mainly those in which a spontaneous fermentation was implicated as part of processes (Table 1). For example, it was described that certain polymers produced by lactobacilli could beneficially affect the water absorption of dough, dough rheology and machinability, its stability during frozen storage, loaf volume and bread staling (Tieking & Gänzle, 2005). Besides, the EPS produced from sucrose by *Lb. sanfranciscensis* LTH2590 presented the potential to affect the rheological properties of the dough, as well as the texture, volume, and keepability of bread (Korakli et al., 2001). In general, EPS isolated from sourdough include mainly HoPS; however, Meulen et al., (2007) described the production of HePS from a sourdough isolate, a strain of *Lb. curvatus*, whose EPS is composed of galactosamine, galactose, and glucose (in relation 2:3:1, respectively). Galle et al., (2011) studied the HePS-producing strains *Lb. casei* FUA3185, *Lb. casei* FUA3186, and *Lb. buchneri* FUA3154, the last was a ropy strain isolated from bread drink (a German fermented grain beverage), regarding their impact on wheat and sorghum sourdough rheology. *Lb. buchneri* FUA3154 showed the highest viscosity at low shear rate when it was grown in MRS. Despite the fact that glycosyltransferase genes responsible for HePS synthesis from the three strains were expressed in sorghum and wheat sourdough, only HePS from *Lb. buchneri* impacted on the rheological properties of sorghum sourdoughs, decreasing resistance to deformation and elasticity.

Regarding the culture conditions that favor the application of EPS-producing strains, Bengoa et al., (2018) analyzed the effect of growth temperature on EPS production of different *L. paracasei* strains isolated from kefir grains and showed that suboptimal temperatures enhanced the EPS yield and polymerization, but their probiotic properties (adhesion to Caco-2 cells and modulation of the epithelial innate immune response) were not affected by this parameter.

Paiva et al., (2016) characterized the EPS produced by novel *Lactobacillus* strains from Brazilian milk or sugar water kefir when they are grown with sucrose as C source. *Lb. kefiranofaciens* 1P3 and *Lb. satsumensis* 10P and 10P2 synthesized EPS composed of glucose, and most of the glucose residues were linked by α -(1,6) glycosidic bonds (~90%) and the estimated molecular weight was 800 kDa. Since the intestinal IgA⁺ B cells were significantly higher in mice that received the EPS, the authors suggested that these EPS might be useful as food additives.

In this direction, Hamet, Piermaria & Abraham (2015) studied the effect of 28 lactobacilli on the texture of acid milk gels and observed that those gels obtained from the fermentation with all the *Lb. paracasei* strains (5 in total) were the ones that presented the highest viscosities, probably due to the presence of a high MW fraction. Nevertheless, the viscoelastic characteristics of the resulting acid gels were different; one of the strains produced a viscous behavior whereas the others presented gel structures.

Another species studied regarding its EPS production was *Lb. fermentum* (Zhang et al., 2011; Leo et al., 2007; Shi et al., 2014). In a recent study of our group (Ale et al., 2016b), the EPS extract from *Lb. fermentum* Lf2 (a strain isolated from an Argentinian cheese with blowing defects) and its impact on the technological properties when applied to yogurts as a natural ingredient, were analyzed. Yogurts with EPS showed higher hardness values than the controls and this difference remained stable during time. The consistency index was also higher for the treated samples at both times evaluated (3 and 25 days), being significantly different for samples with 300 mg/L of EPS extract, while the flow behavior index was lower

for EPS-added yogurts. The thixotropic index was lower for samples with the highest EPS extract concentration at the end of the storage time. Regarding the sensory analysis, no defects were detectable, making it suitable for food applications. Syneresis was also decreased for samples with 600 mg/L of EPS extract at 25 days of storage. These results showed the potential of this extract to be used as a technofunctional natural ingredient, also considering its positive impact on health according to previous studies (Ale et al., 2016a). From another report, sixteen EPS-producing *Lb. fermentum* strains isolated from West African fermented millet dough presented desirable technological and probiotic characteristics *in vitro* (Owusu-Kwarteng et al., 2015). The authors suggested that these strains could function as potential probiotic cultures.

London et al., (2015) applied an EPS-producing strain of *bL. mucosae* as adjunct culture in low-fat yoghurt manufacture. The treated yogurts presented a significant decrease in syneresis and increased viscosity as a consequence of the EPS produced *in situ* during fermentation.

Diverse works described the specific interactions among these polymers and the food matrix in which they are employed. In yogurts, it has been shown by confocal scanning laser microscopy that caseins form a gel and polysaccharides are located in pores containing whey. It is probable that the chemical nature of this EPS was responsible for its incompatibility with proteins aggregates (Hassan et al., 2003). In another study, Folkenberg et al., (2005) described two different sensory profiles which depended on the protein-EPS interactions. They observed two types of microstructures: in one of them EPS were associated with the proteins surrounding the pores, while in the other, incompatibility between the EPS and the protein network existed, causing EPS depletion. In this case, the polymers were found inside the pores. Yogurts with the first type of microstructure presented high ropiness, low serum separation and were more resistant to stirring, and yogurts with the second type of microstructure were less ropy, had high serum separation and showed increased mouth thickness as a result of stirring.

In cheeses, HePS produced by lactobacilli strains such as *Lb. delbrueckii* subsp. *bulgaricus*, *L. helveticus* and *L. casei* promoted water retention and positively modified the texture, avoiding alteration of the structure (Zisu & Shah, 2007). This modification of the textural characteristics often permits the reduction of calories in the final product, for example in low-fat cheeses (Oberg et al., 2015; Zisu & Shah, 2005; Zhang et al., 2016). Accordingly, EPS-producing lactobacilli or EPS (as ingredients) were described as interesting fat replacers to improve the rheological parameters of the final product (Broadbent et al., 2001; Perry, McMahon & Oberg, 1998; Ryan et al., 2015). In this direction, Zhang et al., (2015) studied the yield, textural, proteolysis, melting, and sensory properties of half-fat Cheddar cheese including an EPS-producing *Lb. paracasei* strain. The results revealed that cheeses made with the high yield EPS-producing strain, in combination with the commercial Cheddar culture, presented increased moisture content and yield compared with the half-fat controls. The melting properties were significantly improved as well, and the sensory characteristics were similar to the full-fat controls.

From non-dairy industries, the EPS production by two *bL. suebicus* strains (isolated as responsible of an alteration from ropy ciders) was examined in a semidefined medium (Ibarburu et al., 2015). Both strains were able to use glucose, ribose and xylose as C sources, and synthesize a mixture of complex HePS.

In the light of this information, it is important to remark the relevance of the isolation and characterization of new EPS- producing strains, mainly from artisanal or spontaneously fermented products (even when they were present in a food matrix as non-desirable organisms), representing the principal source of new cultures and ingredients (such as EPS), which are essential to diversify the market of techno-functional food.

FUNCTIONAL ASPECTS OF EPS FROM THE GENUS *LACTOBACILLUS*

The presence of *Lactobacillus* within the intestinal microbiota has been linked to a healthy status of the host and, in general, low levels have been associated with specific health problems as IBS (Irritable Bowel Syndrome; Liu et al., 2017). Although lactobacilli represent just 0.01 % of total faecal bacteria (Walter 2008), it seems that this genus plays an important role in maintaining the normal intestinal homeostasis, knowing that its addition as a probiotic supplement could help balance an aberrant intestinal microbiota (Staudacher et al., 2017). Probiotics are “live microorganisms which, when administered in adequate amounts, confer a health benefit on the host” (Hill et al., 2014). Some strains with scientifically demonstrated probiotic properties were included in diverse functional foods and, although the mechanisms by which they exert their action are uncertain, it has been suggested that the health-promoting effects of EPS-producing strains are related to the biological activities of these biopolymers (Figure 3). In fact, diverse scientific reports indicate that EPS from diverse *Lactobacillus* species can contribute to human health by means of numerous demonstrated effects: prebiotic role, modulation of the immune system, antioxidant, antitumor, antiulcer or cholesterol-lowering activities, etc. (Ruas-Madiedo, Hugenholtz & Zoon, 2002). However, since not all EPS can improve the technological properties of fermented foods (Hassan, 2008), not all are able to promote health benefits (Amrouche et al., 2006), being their chemical structure and MW relevant characters to define their health-promoting function (Hidalgo Cantabrana et al., 2012). The topics mostly supported by an adequate amount of scientific evidence refer to the ability of EPS to act as immunomodulators and prebiotic compounds and will be discussed in independent sections of this chapter.

Figure 3. Health-promoting effects related to EPS produced by lactobacilli. Immunomodulatory properties of EPS.

Besides the physiological role of EPS for the producing bacteria and their relevance for industrial applications, in the last decade there has been increasing evidence about the impact on the human health bias the interaction of the EPS-producing lactobacilli and the host by modulating the immune response.

Notably, carbohydrates were considered as traditional T-cell-independent antigens that do not elicit cell-mediated responses and fail to induce immunologic memory and immunoglobulin class-switching. However, in the last decades, certain microbial polysaccharides have been described as potent immunomodulators with specific activity against both T-cells and antigen-presenting cells such as monocytes and macrophages (Cobb & Kasper, 2005).

Several works in the literature reported the ability of EPS from lactobacilli to elicit immune responses and some authors linked the intrinsic physicochemical characteristics of these molecules with their functional properties (López, 2012), indicating two different types of behaviors or patterns. The first pattern associates functional properties with the presence of acidic substituents as phosphate groups (conferring negative charges) in the molecule, which seem to induce the immune response compared with neutral polymers. For example, the EPS from *bL. delbrueckii* subsp. *bulgaricus* OLL-1073-R1 is composed of two fractions of glucose and galactose: the acidic one (containing phosphate) showed a strong immune profile, inducing the proliferation and activity of macrophages; while the neutral fraction evidenced the opposite behavior, being unable to elicit stimulation (Kitazawa et al., 1998; Nishimura-Uemura et al., 2003; Uemura et al., 1998). The second proposed pattern links the immune response with the MW of the polymer. It has been postulated that EPS having high MW (HMW, $> 10^3$ kDa) could act as strong suppressors of the immune response (Hidalgo Cantabrana et al., 2012), as occurred with the EPS from *Lb. casei* Shirota, a HMW polysaccharide able to induce (by cell culture) the production of diverse cytokines (TNF- α , IL-12, IL-10 and IL-6) in lower extent than EPS⁻ knockout-mutants (Yasuda, Serata & Tomoyuki, 2008). Bleau et al., (2010) showed that murine peritoneal macrophages stimulated with the HMW-EPS-producing *Lb. rhamnosus* RW-9595M, an isogenic mucous variant of the strain ATCC9595, induced lower levels of TNF α and IL-6 than the parental strain, which also evidenced a decrease in IL-10 production. Similarly, Nicolik et al., (2012) reported a suppressive immune response when the HMW-EPS-producing *Lb. paraplantarum* BGCG11 was used for inducing human peripheral blood mononuclear cells (PBMC), in comparison with its novobiocin EPS⁻ mutants. In a study from our group, the EPS from *Lb. fermentum* Lf2 showed a mild suppressive profile when administered to mice, increasing s-IgA levels and reducing the proinflammatory cytokine IL-6 in the small intestine when added in a dairy matrix (Ale et al., 2016a). In this case, based on preliminary evidence indicating a relatively low MW (< 100 kDa in average) and the absence of charged substituents, the observed mild stimulation of immune cells when administered to mice could obey the patterns previously proposed by Bleau et al., (2010) and López et al., (2012). In these cases, a HMW-EPS could be purified from the crude extract, consisting of a β -glucan (1.23×10^3 kDa) which was able to inhibit the rises of TNF- α levels in peripheral blood mononuclear cells pre-treated with lipopolysaccharide (LPS) or phytohemagglutinin (PHA). The results indicate a role of this polysaccharide in modulating the immune response after exposure to agonists such as bacterial LPS.

The cytokine profiles produced by EPS are not always clear. For example, EPS from *Lb. rhamnosus* KL37 and *Lb. reuteri* 115 were able to stimulate the simultaneous secretion of

both anti-inflammatory (IL-10) and proinflammatory (TNF- α and IL-6) cytokines from peritoneal mouse macrophages (Ciszek-Lenda et al., 2011). Vinderola et al., (2006) demonstrated that the oral administration of a high dose of kefiran, an EPS produced by *Lb. kefiranofasciens*, showed an immunomodulation (mediated by IgA, IL-2, IL-6, IL-10, TNF- α) at the level of large intestine and blood, suggesting a potential role in intestinal homeostasis. Additionally, another study showed that the systemic administration of *Lb. rhamnosus* KL37C EPS stimulated a significant decrease in the serum concentration of type II collagen-specific IgG antibodies in a murine model of mild rheumatoid arthritis, consequently improved the condition (Nowak et al., 2012).

The role of polysaccharides in the balance of the immune status associated with inflammatory disorders caused by infections has been also reported. One of the traditional phenotypic features tested during *in vitro* probiotic characterization is the ability to coaggregate with pathogens, since it is believed that co-aggregation decreases the accessibility of the harmful microorganisms to the intestinal epithelium (Castro-Bravo et al., 2018). In this sense, the activities against *Candida* of *Lb. rhamnosus* GG, its EPS deficient mutant, and the purified EPS were analyzed, showing that the EPS layer might be involved in the reduction of hyphal formation and in the competition with *Candida* during adhesion to vaginal epithelial cells (Allonsius et al., 2017). Another study with a *Lb. paracasei* subsp. *paracasei* BGSJ2-8 EPS-deficient mutant, producing an EPS with a different composition, indicated that the wild-type EPS is essential to reduce *Escherichia* (*E.*) *coli* association with Caco-2 cells, while the mutant strain was not able to counteract this interaction (Živković et al., 2016). This highlights the importance of EPS composition and not only EPS production in the potential interaction with pathogens. Also, EPS isolated from *Lb. delbrueckii* subsp. *delbrueckii* were able to significantly down-regulate the expression of enterotoxigenic *E. coli*-induced proinflammatory cytokines (IL-6, IL-8 and MCP-1) in porcine intestinal epithelial cells (Wachi et al., 2014). Regarding *in vivo* experiments, different animal models have been used to study how EPS-producing strains interfere with pathogen activity. For instance, *Lb. johnsonii* FI9785, a poultry derived isolate producing two different EPS, was effective to suppress the colonization and persistence of *Clostridium* (*Cl.*) *perfringens* in poultry and to reduce colonization by *E. coli* in the small intestine (Dertli et al., 2013). In case of the crude EPS from *Lb. fermentum* Lf2, it showed a mild protection against *Salmonella* infection in a survival murine model when suspended in milk, in a dose feasible to be used as a food ingredient. In this same study, the survival proportion for the treated group (31%) resulted significantly higher than that of the control group (9%), thus representing another mode of action of this EPS to elicit positive health benefits (Ale et al., 2016a). This property could be related with the increased s-IgA levels in the intestinal fluid of mice also observed for this extract when used as an ingredient in yogurts. Similar survival rates were observed by Nagai et al., (2011) when evaluating the effect of an EPS from a strain of *Lb. delbrueckii* subsp. *bulgaricus* on the influenza virus infection after 21 days of administration of yogurts. Although they evaluated the capacity of EPS against a virus, the survival of mice ranged from 0% for the control groups to 38.9% for diverse EPS-fractions.

The molecular mechanisms by which lactobacilli interact with immune cells have not been entirely elucidated. The highly multifunctional Toll-like receptor (TLR) family, which are able to recognize a vast range of extracellular bacterial products (Patten & Collett, 2013; Patten et al., 2014), could mediate these interactions. Particularly, TLR-2 is known to interact with a diverse range of microbial components (Akira, Uematsu & Takeuchi, 2006; Takeda,

Kiasho & Akira, 2003). The LPS receptor, TLR-4 (Hoshino et al., 1999), is also a promising candidate, and a response in which a combination of TLR-2 and TLR-4 takes place was also suggested (Wachi et al., 2014).

It has been previously proposed that bacterial EPS could exert their immunomodulatory action via the mannose receptor (Chabot et al., 2001). However, the feasibility of this hypothesis is questionable due to the structural heterogeneity of microbial EPS. Taking into account the immune parameters and the diverse responses according to their physicochemical characteristics (high or low MW, presence or absence of charged substituents and even, ramifications), EPS from lactobacilli with an evident positive health effect could be included in the diet of patients suffering diseases associated with an increased inflammatory status, such as allergy and inflammatory bowel disease, or other auto-immune disorders, as well as in functional foods formulated for the elder population.

EPS as Prebiotics

Prebiotics are non-viable substrates that function as nutrients for beneficial microorganisms harbored by the host (probiotic strains and indigenous microorganisms). Thus, a prebiotic should favor a metabolism biased towards health-promoting microorganisms within the indigenous ecosystem. According to the consensus statement by ISSAP (International Scientific Association for Probiotics and Prebiotics), the definition of a prebiotic has been recently modified to “a substrate that is selectively utilized by host microorganisms providing a health benefit” (Gibson et al., 2017). Health effects of these substances include benefits not only to the gastrointestinal tract (inhibition of pathogens and immune stimulation), but also to the cardiometabolism (reduction in blood lipid levels and effects upon insulin resistance), mental health (metabolites that influence brain function, energy and cognition) and bone (mineral bioavailability), among others (Gibson et al., 2017; Collins & Reid, 2016). In addition, the term synbiotics refers to a combination of both, probiotics and prebiotics, and a synergic interaction among them (Cencic & Chingwaru, 2010).

The catabolism of prebiotic carbohydrates by the metabolic activity of intestinal bacteria produces mainly three SCFA (Short Chain Fatty Acids): acetate, propionate and butyrate. Thus, the prebiotic substrates can induce increased values of the levels of these acids in healthy individuals as end products of human colonic bacteria metabolism (Lecerf et al., 2012). SCFA contribute to the normal large bowel function and prevent pathology through their actions in the lumen and on the colonic musculature and vasculature, and through their metabolism by colonocytes. The most abundant SCFA in the colon is acetate and represents, in general, more than half of SCFA detected in faeces (Louis et al., 2007). It has been shown that bifidobacteria can protect the host against enteropathogenic infections through the production of this acid (Fukuda et al., 2011). In addition, this acid and propionate are produced mainly by species belonging to the *Bacteroidetes* phylum, while butyrate is produced predominantly by the metabolism of some species of the *Firmicutes* phylum (Walker et al., 2005). Acetate has also been related to appetite reduction through its interaction with the central nervous system (Frost et al., 2014) and the three SCFA have been associated with intestinal anti-inflammatory properties (Tedelind et al., 2007). Particularly,

butyrate is thought to play a role in maintaining a normal colonocyte population and participates in the motility of the colon, reducing inflammation, increasing visceral irrigation, inducing apoptosis and inhibiting the progression of tumor cells, properties that contribute with the prevention of colorectal cancer (Canani, 2011; Zhang et al., 2010). It was also described that, as a result of a lower luminal pH, all SCFA can inhibit pathogens (Gibson & Roberfroid, 1995).

The most studied prebiotic compounds include inulin (composed by fructose), fructooligosaccharides (FOS), galactooligosaccharides (GOS) and glucooligosaccharides such as β -glucans. In this scenario and taking into account their analogous chemical composition, EPS from lactobacilli can be considered *per se* as prebiotic substances. In some cases, and depending on their chemical nature, they can be fermented by the gut microbiota and, in consequence, associated with a SCFA increase. For example, Zhang et al., (2017) found that the EPS produced by a strain of *Lb. plantarum* was able to improve the oxidative and health conditions of the host intestinal tract in an aging mice model induced with D-galactose. They reported high contents of nitrogen oxides together with gut microbiota regulating activities, evidenced by increased levels of SCFA and higher counts of some members considered beneficial (*Blautia* and *Butyricoccus*), together with a simultaneous reduction of microbial groups recurrent in humans with inflammatory diseases. Bello et al., (2001) and Korakli, Gänzle & Vogel (2002) revealed that EPS from strains of *Lb. sanfranciscensis* have bifidogenic effects on cultures of fecal bacteria and monocultures of *Bifidobacterium* (*Bf.*) *breve*, *Bf. bifidum*, *Bf. infantis* and *Bf. adolescentis*. More recent studies also demonstrated the bifidogenic properties of EPS isolated from strains of *Lb. rhamnosus* and *Lb. plantarum* (Das, Baruah & Goyal, 2014; Polak-Berecka et al., 2013). Hamet et al., (2016) evaluated the activity of kefir on intestinal bacterial populations in BALB/c mice and confirmed by DGGE its bifidogenic effect. Furthermore, a study by Tsuda and Miyamoto (2010), for which an EPS isolated from an EPS-overproducing mutant strain of *L. plantarum* was used, described an increase in the proliferation of a number of other known beneficial bacteria, including *Pediococcus* (*Ped.*) *acidilactici* ID-7 and 5885, *bL. casei* L-49, *Lb. plantarum* IFO 3070 and *Lb. delbrueckii* subsp. *lactis* 306701. Besides, the EPS from *Lb. plantarum* mutant can be used by the probiotic parental strain *Lb. plantarum* 301102.

In a recent study (Ale 2018), we demonstrated using a mice model that when added as a food ingredient in yogurts, the EPS from *Lb. fermentum* Lf2 exerted a possible prebiotic role reflected in an increase of SCFA levels (mainly acetate and butyrate) in faeces, accompanied by an increase in the levels (determined by qPCR) of the bacterial cluster XIVa of *Clostridium* (also known as *Cl. coccoides* group) that are known to produce these beneficial acids for health. When this EPS was combined with the probiotic strain *B. animalis* subsp. *lactis* INL1, a bifidogenic effect throughout the treatment was observed, improving the effect conferred by both individual ingredients, a fact that could be associated with a possible synergism between them suggesting a possible symbiotic role.

In all the cases described, it would be necessary to demonstrate the effective health benefit associated with the recent definition of prebiotic by means of human clinical trials or, at least, animal *in vivo* assays. Taking into account the current difficulty of some countries in carrying out clinical studies, as well as their high costs, it would seem reasonable that these results will be provided by research groups from highly developed countries.

Other Health Effects Associated with EPS

A recent perspective for EPS is related to their antitumor and antioxidant (property related to the anticancer activity) bioactivities, and their ability to inhibit the biofilm formation in pathogenic bacteria as well, as revised by Jiang and Yang (2018). In this review, it has been summarized that eight strains of *Lb. plantarum* had antitumor and antioxidant activities, being effective (at least *in vitro*) on colonic, liver, gastric, colon and pancreatic cancer, as well as on breast adenocarcinoma and oxidative stress. The authors suggested the use of these EPS as antitumor adjuvants. However, this claim is too hasty considering that anti-cancer properties are attributed to these molecules based exclusively on *in vitro* tests and, *in vivo* or human clinical studies result mandatory to effectively demonstrate these results, as mentioned above. In another recent work, Riaz et al., (2018) described the functional properties of the EPS from strains of *Lb. rhamnosus* isolated from breast milk. They found the EPS exhibited potent antioxidant activity, antitumor activity against Caco-2 cells and strong antibacterial activities against *E. coli* and *Salmonella* Typhimurium, corresponding to an excellent biofilm inhibition activity against *S. Typhimurium* *in vitro*. Furthermore, cell bound polysaccharides (CPS) were studied regarding their functional properties. Li et al., (2015) studied the CPS of a strain of *Lb. helveticus*, a HePS with an average MW of 1.83×10^2 kDa composed of glucose, mannose, galactose, rhamnose and arabinose. Preliminary *in vitro* tests revealed that this polymer significantly inhibited the proliferation of cancer cell lines. In another previous work, Li et al., (2014) showed that the same EPS presented potent antioxidant effects, chelating ability on ferrous ion and antibiofilm activities by inhibition of three biofilm forming foodborne pathogenic bacteria.

Antimutagenic activity (binding ability to different mutagens such as heterocyclic amines, 4-Nitroquinoline-N-oxide and 2-Nitrofluorine) from EPS-producing lactobacilli (*Lb. plantarum* and *Lb. rhamnosus*) was also reported (Tsuda, Hara & Miyamoto, 2008; Thapa & Zhang, 2009). In one of these works, the authors proposed a binding mechanism of ion-exchange and hydrophobic bonds by which the EPS would bind mutagens in the intestine (Tsuda et al., 2008).

In addition, there is some evidence that certain EPS have a protective role against microbial toxins, as reported for the EPS of *Lb. rhamnosus* ATCC9595, with demonstrated cholera toxin-binding activity (Kim et al., 2006). Similarly, kefiran counteracted the cytotoxic effect of extracellular toxins produced by *Bacillus cereus* in cell cultures (Ruas-Madiedo et al., 2010).

EPS have also been related to alleviate acetic acid-induced experimental colitis model in rats (Şengül et al., 2006). In this work, the effect of the EPS-producing *Lb. delbrueckii* subsp. *bulgaricus* B3 strain was compared with another one with low ability to synthesize EPS (*Lb. delbrueckii* subsp. *bulgaricus* A13), analyzing the role of the EPS dose on colitis. Authors observed that those rats treated with both EPS-producing strains presented lower histologic scores of colonic damage than the control group, demonstrating an improvement by *Lb. bulgaricus* B3. Consequently, a probiotic role associated with the high production of EPS was suggested for this particular strain, showing its therapeutic potential.

An important aspect of the EPS functionality obeys to their general resistance to gastrointestinal conditions (Khalil et al., 2018) resulting from the action of the gastrointestinal tract of the host. Sönmez, Önal Darılmaz, and Beyatli (2018) evaluated the protective effects

of EPS production on resistance to gastrointestinal digestive conditions and to oxalate by probiotic strains of the species *Lb. rhamnosus*, *Lb. fermentum* and *Lb. brevis*. The high-EPS-producing *Lb. fermentum* IP5 and *Lb. brevis* YG7 strains showed high oxalate-degrading activity, whereas the low-EPS-producing strain *Lb. fermentum* BP5 demonstrated low ability to degrade oxalate. These results suggest that dietary supplementation with *Lb. fermentum* IP5 could prevent oxalate stone disease, assuming that the EPS produced by this strain is the responsible of this beneficial response.

EPS from lactobacilli have also been related to the adsorption of heavy metals. For example, Feng et al., (2012) demonstrated the biosorption of Pb(II) ions by an EPS isolated from *Lb. plantarum* 70810. EPS also demonstrated antioxidant and metal ion chelating activities (Li et al., 2014; Kodali & Sen, 2008). EPS from *Lb. rhamnosus* E/N (Polak-Berecka et al., 2013), *Lb. plantarum* C88 (Zhang et al., 2013), *Lb. plantarum* LP6 (Li et al., 2013) and *Lb. helveticus* MB2-1 (Li et al., 2014) have all exhibited moderate free radical scavenging and metal ion chelating activities in *in vitro* systems.

Some other studies associate the administration of EPS with modifications on the cardiometabolism. For example, spontaneously hypertensive stroke-prone rats fed with kefir exhibited significantly lower blood pressure and lower levels of cholesterol and triglycerides in serum and liver, when compared to untreated rats (Maeda et al., 2004). Additionally, EPS fractions from *Lb. casei* LC2W exhibited a moderate reduction in blood pressure (Ai et al., 2008), without significantly affecting the heart rate. In this direction, Tok and Aslim (2010) suggested that an EPS isolated from *Lb. delbrueckii* subsp. *bulgaricus* was able to sequester cholesterol from conditioned media *in vitro*. Sasikumar et al., (2017), who characterized the EPS extract produced by the strain *Lb. plantarum* BR2, described that this polymer consisted of a HMW glucomannan with antioxidant and lowering cholesterol activities, together with antidiabetic potential.

CHEMICAL STRUCTURE AND FUNCTIONAL/ TECHNOLOGICAL PROPERTIES RELATIONSHIP

Many structural factors were reported to affect EPS properties, such as monosaccharide composition, molecular size, glucosidic bond, charge, presence of side chains and rigidity of the molecules (Salazar et al., 2014). From their functional aspects, EPS having negative charges (phosphate or sulfate), glucose and/or galactose in their composition, and/or low molecular weights were shown to act as mild stimulators of immune cells, whereas neutral polymers with higher molecular weights exhibited a suppressive profile (Caggianiello, Kleerebezem & Spano, 2016; Yasuda, Serata & Sako, 2008). In general, small negative EPS are thought to be able to stimulate professional immune cells and larger neutral EPS believed to possess more immune-suppressive qualities (López et al., 2012; Hidalgo-Cantabrana et al., 2012). Besides, an interrelation between the types of bonds of the HePS and their rigidity has also been found: $\beta(1,4)$ bonds result in more rigid chains than $\alpha(1,4)$ or $\beta(1,3)$ bonds. In consequence, β bonds are able to give more chain stiffness compared to α bonds (Jolly et al., 2002). Side chains can also affect stiffness and, therefore, increase their efficiency as thickeners.

It was also described that EPS surrounding the bacterial surface, mainly those having a high MW, might reduce adherence to intestinal cells, and even to abiotic surfaces, due to shielding of surface macromolecules acting as adhesins. For example, deletion of the *cps2*-like gene cluster on *Lb. plantarum* Lp90 improved its adhesion to Caco2 cells in comparison with its parental strain (Lee et al., 2016). In accordance to this result, Dertli, Mayer, and Narbad (2015) suggested that EPS may hinder molecular interactions with host epithelial membranes. HMW-EPS reduce the adhesion capacity of the EPS-producing strain *in vitro*, which may also have a negative impact on intestinal colonization, as demonstrated for some *Bifidobacterium* strains (Castro-Bravo et al., 2017). In fact, the same conclusion was previously reported for *Lb. rhamnosus* GG through deletion of the priming-GTF, which abolished the synthesis of a long, galactose-rich EPS (Lebeer et al., 2009). However, while the non EPS-producing mutant presented good adhesion *in vitro*, an *in vivo* study showed that it was more sensitive toward host innate defenses; thus the EPS would favor its persistence in the murine gut (Lebeer et al., 2011). Branches may also be related to EPS functionality, Huazano-García and López (2013) suggested that there is a relationship between the structure of fructans (chain length and branches) with the production of SCFA. They observed that branched fructans induced higher levels of SCFA than linear polysaccharide.

Apart from the influence of the chemical characteristics of these molecules on their functionality, their impact on the technological properties was studied as well. Some structure/function relationships have been proposed, for example, polysaccharides that present $\beta(1,4)$ linkages were associated with stiffer chains able to provide high consistency to the food matrices. Those containing $\alpha(1,6)$ linkages in the main chain, such as dextran, presented both good thickening and stabilizing effects (Zannini et al., 2016). Furthermore, polysaccharides with high molecular masses and a stiff conformations are important in order to obtain an increase in viscosity (De Vuyst & De Vin, 2007).

Other important physicochemical characteristic is the degree of branching, which may contribute to the stiffness of the polymer, while their primary structure (MW, monomer composition, type of linkages, presence of side-groups) also affect the rheology of EPS solutions (Tuinier et al., 2001).

Regarding the influence of the charge on the technological properties, it has been described that neutral EPS contributed to viscosity but not to elasticity. The contrary behavior was observed for negatively charged EPS which were able to interact with positive charges of caseins (Duboc & Mollet, 2001). The amount of EPS is not always the most important parameter for viscosity, in contrary to its structure which is the determinant for the interactions with casein. For this reason, although LAB synthesize EPS in small quantities, these could be enough to deliver rheological changes on the texture of dairy products.

When neutral or positively low charged EPS interact with caseins, a depletion effect can occur, leading to the formation of protein and EPS aggregates in the serum phase (Buldo et al., 2016; Costa et al., 2012). This phenomenon has been related to decreasing viscoelastic properties due to the interference of the EPS with the protein network formation, or increasing viscoelastic properties, as a consequence from the formation of a dense casein network (Amatayakul et al., 2006a; Hassan et al., 2003; Buldo et al., 2016). The presence of EPS in the serum phase also leads to higher water-binding capacity, resulting in lower syneresis and high viscosity (Gentès, St-Gelais & Turgeon, 2013). Future studies are required to establish clearer structure-functional/technological properties relationship.

CONCLUSION

An increasing number of EPS produced by *Lactobacillus* strains have been isolated and characterized in the last few years, evidencing a high diversity among them. Despite the unknown physiological role of EPS in the producing bacteria, it seems to be related to the recognition of the external environment, thus exerting a protective effect.

The integral characterization (structure, MW, presence of charged residues, type of branches, etc.) of these macromolecules is essential when EPS (as an ingredient) or the EPS-producing strain is included in a food matrix, since recent studies strongly associated these characteristics with their rheological and health-promoting properties. In this way, the characterization of the EPS molecule to be added in a food matrix would allow to infer the techno-functional properties of the final product.

Although their low production compared with EPS produced by non-LAB bacteria, EPS from lactobacilli are, from their technological point of view, able to improve the rheological properties of dairy products. According to their structural and chemical properties, in some cases, even present in low concentrations in the final product, they are adequate to positively change the rheology, as occurs in some low-fat cheeses. Furthermore, some EPS produced by lactobacilli have the ability to exert a wide range of beneficial effects on human health: immunomodulation, prebiotic role, antioxidant, anticarcinogenic, among others. As these properties were extensively demonstrated *in vitro* and at high EPS concentrations, an interesting challenge for the future will be the elucidation of the physiological mechanisms of actions and the demonstration, by *in vivo* studies, of the real effect on the intestinal environment when the EPS are included in applicable concentrations in a real food matrix.

The use of HoPS or HePS from *Lactobacillus* or the EPS-producing bacteria could have a promising future for their application as potential techno-functional ingredients for the design of novel foods. An interesting alternative is the optimization of the environment conditions to increase the yield of EPS when they are to be used as food ingredients. A further possibility is to use engineered food-grade lactobacilli strains with the aim of specifically modifying certain genes associated with the polymer synthesis, for the design of new fermented foods.

ABSTRACT

Nowadays, many studies have reported the potential spore-forming lactic acid bacteria (SFLAB) with the high performance of lactic acid production and high specificity of lactic acid isomers. This group of bacteria belongs to the genera *Bacillus* and *Sporolactobacillus*. Most of the SFLAB are homofermentative bacteria which can only produce lactic acid from sugar. Additionally, these SFLAB strains are dominant to produce an optically pure D(-)- or L(+)-lactic acid which is preferred to the specific application, especially in the manufacturing of biodegradable and biocompatible polylactic acid (PLA) which can be a replacement of synthetic plastics derived from petroleum resources. Considering the general characteristics of SFLAB, both genera are endospore-forming, rod-shaped, and gram-positive bacteria. The members of the genus *Bacillus* include *B. coagulans*, *B. stearothermophilus*, *B. licheniformis*, *B. subtilis*, and *Bacillus* sp. All of these *Bacillus* species could grow and form endospore under aerobic condition. On the other hand, the genus *Sporolactobacillus* differs from strains of *Bacillus* species in its response to oxygen, because the optimal growth has been found in microaerophilic or anaerobic condition. At the present, increasing the *Sporolactobacillus* species has been reported, including *S. inulinus*, *S. laevolacticus*, *S. nakayamae*, *S. racemicus*, *S. terrae*, *S. kufoensis*, *S. lactosus*, *S. putidus*, *S. vineae*, *S. pectinovorans*, *S. shoreicoticis*, *S. shoreae* and *S. spathodeae*. A few years ago, the novel genus

Terrilactibacillus was discovered and reported as a potential spore-forming lactic acid bacterium. The type species is *Terrilactibacillus laevilacticus* which has individual characteristics compared to the others. Currently, SFLAB have been applied in the wide range of applications, including biochemical compounds, probiotics, and commercial enzymes. This chapter describes the recent status of SFLAB strains and their advantages which could be found from the studies and their applications.

INTRODUCTION

Generally, lactic acid production has been well recognized from the biological conversion of carbohydrate by lactic acid bacteria (LAB). Plenty information of this bacteria group can be easily found. The phenotypic characterization of this group is Gram-positive, fastidious, non-spore forming rods or cocci which mainly produce lactic acid from carbohydrates under anaerobic environment. The group members of LAB comprise of genera *Lactobacillus*, *Leuconostoc*, *Pediococcus*, and *Streptococcus* (Lui et al., 2014). At the present, spore-forming lactic acid bacteria (SFLAB) are one of the potential lactic acid producers, including the genera *Bacillus* and *Sporolactobacillus*. Historically, the definition of a spore-forming organism was originally referred to the genus *Bacillus* that are able to form endospores which are heat-resistant bodies that were not easily killed by mere boiling (Cohn, 1876; Koch, 1876). The ability to form endospores of the bacteria results in resistance to unfavorable growth conditions. Later, the first classification of endospore-forming bacteria was proposed by de Bary (1884) and by Hüppe (1886) but the generic name *Bacillus* was more used for various rod-shaped bacteria (Fritze & Clausen, 1995). However, to define as SFLAB, the genus *Bacillus* was respected as comprising spore-bearing rod producing lactic acid, which is facultative anaerobic or aerobic catalase positive, following the 8th edition of Bergey's Manual Determinative Bacteriology (Abriouel et al., 2011). Another SFLAB member is defined to the genus *Sporolactobacillus*. These bacteria strains were classified using the phylogenetic data between *Lactobacillaceae* and *Bacillaceae* (Nakayama & Sakaguchi, 1950). The phenotypic characterization was described as Gram-positive, microaerophilic, mesophilic rods, and catalase negative. Comparing to LAB, the group members of SFLAB were smaller discovered. Nowadays, some *Bacillus* and *Sporolactobacillus* species have been reported as lactic acid producer, including *B. coagulans*, *B. stearothermophilus*, *B. licheniformis*, *B. subtilis*, *Bacillus* sp., *S. inulinus*, *S. laevolacticus*, *S. nakayamae*, *S. terrae*, *S. kofuensis*, *S. lactosus*, *S. putidus*, and *Sporolactobacillus* sp. (Abdel-Rahman et al., 2013; Doores, 2014). Besides, most of SFLAB strains produced an optically pure lactic acid isomer (D(-) or L(+)-lactic acid) with a high lactic acid titer, depending on their cultivation conditions. Additionally, the recent novel genus *Terrilactibacillus* has been found as a promising D-lactic acid producer. This finding indicates that the novel strains could be a candidate for D-lactic acid production (Prasirtsak et al., 2016; 2017). Besides, the several performances of SFLAB to produce a wide range of products using the alternative substrates are now being developed.

Recently, the spore-forming lactic acid bacteria are being explored for the variety of applications. Besides their ability to produce lactic acid, the probiotics aspect is being widely studied. Additionally, another feature of this SFLAB group is the source of enzymes which can be applied in food and non-food industries. This information indicates that SFLAB could

be a candidate for a variety of industry. This chapter updates the research regarding the spore-forming lactic acid strains and highlights the utilization of SFLAB strains in various applications.

SPORE-FORMING LACTIC ACID BACTERIA

SFLAB are microorganisms which mainly produce lactic acid and relates to lactic acid bacteria (LAB) strains. In particular, due to the remarkable and resistant dormancy of their spores and response to oxygen these characteristics are used to differentiate between SFLAB and LAB. In order to obtain interesting strains, several environment resources, including soil, foods, and feed were used for screening and isolation (Doores, 2014; Chang & Stackebrandt, 2014; Abriouel et al., 2011). Previously, the genus *Bacillus* and *Sporolactobacillus* were classified as a member of SFLAB. Besides, some basic characterizations of these 2 genera were different. The genus *Bacillus* is facultatively anaerobic or aerobic and catalase positive. Most of the *Bacillus* strains are able to grow and ferment the hexoses and pentoses to L(+)- or DL(-)-lactic acid. Moreover, they can produce lactic acid in the thermal fermentation (Abdel-Rahman et al., 2013). On contrary, *Sporolactobacillus* strains were described as the mesophilic, catalase negative, microaerophilic, and produce D(-)-lactic acid by a homofermentative pathway (Doores, 2014; Chang & Stackebrandt, 2014). Recently, the novel genus *Terrilactibacillus* has been discovered and published as a Gram-positive, catalase-positive, facultatively anaerobic, spore-forming, rod-shaped bacterium. It was found as the homofermentative D(-)-lactic acid producer (Prasirtsak et al., 2016). Additionally, their differentiating characteristics were also clarified (Table 1).

The Genus *Bacillus*

The genus *Bacillus* has long been known to be spore-forming bacteria due to its endospore formation in adverse environments. The generic name *Bacillus* was established by a German Botanist, Ferdinand Cohn, who has discovered rod-shaped bacteria which grow in filaments (Cohn, 1872). Later, in this genus the resting stages resistant to various adverse environments were detected; it was not killed by heat (Cohn, 1876; Koch, 1876). According to its heat-resistant behavior, it was found that the genus *Bacillus* was able to form endospores that are more resistant than vegetative cells to heat, drying, and other destructive agents (Gordon et al., 1973). The classification of *Bacillus* species was originally proposed by de Bary (1884) and Hüppe (1886). However, the *Bacillus* lactic acid producing strains were officially published in the Bergey's Manual of Determinative Bacteriology. According to the publication, the genus *Bacillus* was defined as the spore-forming rods capable of lactic acid production. Additionally, the general characterizations of the strains are Gram-positive, facultatively anaerobic or aerobic, and catalase positive (Abriouel et al., 2011; Zeigler and Perkins, 2008).

Bacillus strains have been utilized in a wide range of the applications, including enzyme technology, probiotics, food industry, medicine, cosmetics, agriculture, and chemistry (Poudel et al., 2016). In order to obtain the new functions and improve existing applications,

the novel *Bacillus* strains have been continuously screened. Recently, the *Bacillus* strains have been recognized as a potential L(+)-lactic acid producing strain. The list of *Bacillus* lactic acid producing strains includes *B. coagulans*, *B. stearothermophilus*, *B. licheniformis*, *B. subtilis*, and new isolated *Bacillus* species. All these *Bacillus* strains produced an optically pure L(+)-lactic acid (97 - 100%) (Poudel et al., 2016). Interestingly, *Bacillus* species are able to grow and produce L(+)-lactic acid by using a simple mineral salts medium with a small amount of yeast extract (Poudel et al., 2015; Wang et al., 2011; Heriban, 1993). Furthermore, this species can tolerate high temperatures (45 - 60°C) and pH (5.0 - 9.0) (Thitiprasert et al., 2017; Poudel et al., 2015; Ma et al., 2014; Ye et al., 2013; Ou et al., 2009; Ramos et al., 2000). These characteristics indicate the several advantages can be gained in the L(+)-lactic acid fermentation by these *Bacillus* species. First, to operate the fermentation at high temperature could reduce the cooling cost, comparing to mesophiles which require the temperature control during fermentation (Abdel-Rahman et al., 2013). Second, to control the high-temperature fermentation would prevent contamination problems (Ye et al., 2013). Third, there are some researches that have claimed that the rate of L(+)-lactic acid production could be improved by operating the fermentation at high temperature (Heriban et al., 1993). Fourth, to use the thermophilic *Bacillus* species could provide the benefit on the simultaneous saccharification and fermentation (SSF) of lignocellulosic biomass with hydrolytic enzymes (cellulase, amylase) at an optimum temperature (Budhavaram & Fan, 2009; Maas et al., 2008a; Ou et al., 2011; Patel et al., 2006). In addition, the thermotolerant *Bacillus* species, including *B. coagulans* and *B. licheniformis* have been used for open fermentation using nonsterile media at high temperature (Wang et al., 2011; Wang et al., 2019).

Table 1. Characteristics of *Bacillus*, *Sporolactobacillus* and *Terrilactibacillus*

Characteristic	<i>Bacillus</i>	<i>Sporolactobacillus</i>	<i>Terrilactibacillus</i>
Cell form	Rods	Rods	Rods
Endospore position	Terminal	Terminal/subterminal	Terminal
Oxygen requirement	Aerobe or facultative anaerobe	Facultative anaerobe	Aerobe or facultative anaerobe
Growth temperature (°C)	Wide range (psychrophilic to thermophilic species)	15-45	20-45
pH range	Wide range (acidophilic to alkaliphilic species)	5-8	5-8.5
Maximum NaCl (%) for growth	Some are halophilic, some are salt tolerant	10	3
Catalase production	+	-	+
Oxidase	+/- depended on species	-	-
Nitrate reduction	+/- depended on species	-	+
Homolactic acid fermentation	Depended on species and cultivation conditions	+	+
Isomer of lactic acid	Most optically pure L(+)-lactic acid	D(-)-lactic acid	D(-)-lactic acid
G+C mol %	32-69	43-50	42.6

In sugar metabolism, the *Bacillus* species are able to metabolite hexose and pentose sugars via the Embden-Meyerhof-Parnas and the pentose-phosphate pathway, respectively. The maximum lactic acid yield that could be achieved was up to 1 g/g-consumed sugar (Patel et al., 2006; Ye et al., 2013, 2014). Currently, the alternative carbohydrate resources have been extensively determined for lactic acid production using the *Bacillus* strains. A variety of crops have been being investigated for lactic acid production, including lignocellulosic

biomass (e.g., crop residues), sucrose (e.g., sugar cane and beet molasses), starchy materials (e.g., cassava, potato, cereal-based products), and food-wastes (Abdel-Rahman et al., 2013; Poudel et al., 2016). However, the use of these alternative carbohydrates is still limited; in particular these materials require pretreatments that form the inhibitor compounds (e.g., furfural, 5-hydroxymethylfurfural, and some organic acids) resulting in decreasing the performance of microbial lactic acid production (Jönsson and Martín, 2016). On the other hand, there are some reports that have investigated the fermentation of lactic acid in lignocelluloses containing inhibitors medium. It was found that the *Bacillus* strains could tolerate to the pretreatment inhibitors and convert them to less-toxic substance. Especially, *B. coagulans* has been reported the resistant performance of the inhibitors at certain levels (Peng et al., 2013; Ye et al., 2013; Bischoff et al., 2010; Zhang et al., 2014).

Commonly, lactic acid bacteria producing strains employ a facultative anaerobic environment to produce lactic acid because of their lack of an oxygen electron acceptor, leading to a small amount of lactic acid production although they are able to grow in an environment presenting oxygen (Hofvendahl & Hahn-Hägerdal, 2000; Bobillo et al., 1991). Considering to the *Bacillus* strains, they can produce lactic acid as a main metabolite either under strict anaerobic or aerobic condition (Thongpim et al., 2014; Thitiprasert et al., 2017).

In view of the aforementioned studies, it should be noted that the *Bacillus* lactic acid producing strains have been gained popularity as an interesting lactic acid producer. Particularly, *B. coagulans*, *B. subtilis*, *B. licheniformis*, and *B. thermoamylovorans* have been recognized as the promising L(+)-lactic acid strain (Poudel et al., 2016). Furthermore, the *Bacillus* species are recently determined for other applications, including probiotics, thermostable enzymes, and antimicrobial activity (Konuray & Erginkaya, 2018; Elshaghabee et al., 2017; Pandey 2017; Tolieng et al., 2018).

The Genus *Sporolactobacillus*

A spore-forming and homofermentative lactic acid bacteria in the genus *Sporolactobacillus* was originally isolated from chicken feed by Kitahara and Suzuki (1963). *Sporolactobacillus inulinus*, the type species was a Gram-positive, catalase negative, microaerophilic, mesophilic rods, producing exclusively D(-)-lactic acid, motile by a small number of peritrichous flagella and formed oval endospores in the terminal position (Kitahara and Suzuki, 1963; Suzuki & Kitahara 1964). Later, another species of spore forming lactic acid bacteria were isolated from the soil of the plant rhizospheres (Nakayama & Yanoshi, 1967a, 1967b). The species showed different catalase activity and an enantiomeric form of lactic acid production. In the group of catalase-positive which consisted of *B. laevolacticus* and *B. racemilacticus*, optically pure D(-)-lactic acid and DL-lactic acid were produced, respectively. For the catalase negative strains which related to *S. inulinus* the production of DL-lactic acid were found. However, the bacterial names proposed by Nakayama & Yanoshi (1967a) were not included in the Approved Lists of Bacterial names (Skerman et al., 1980). According to the proposal of Andersch et al. (1994), they determined the strains of *B. laevolacticus* genetically and phenotypically distinct from other lactic acid-producing, aerobic, spore-forming bacteria. Then the name *B. laevolacticus* was revived and assigned to the same taxon as it was originally located, following the International Code of Nomenclature of Bacteria. Based on the properties of the single strain resulted in the name *B. racemilacticus*

could not be validated (Andersch et al., 1994). In the year 2006, from the results of phylogenetic analyses, as well as chemotaxonomic and phenotypic characterization revealed that *B. laevolacticus* was not included in the cluster of the genus *Bacillus* but should be reclassified into the genus *Sporolactobacillus*. Therefore, *B. laevolacticus* was reclassified as *S. laevolacticus* comb. Nov. (Hatayama et al., 2006). Initially, the species were considered to be similar to *Bacillus* and *Lactobacillus* (Kitahara & Lai, 1967). Furthermore, there are more studies on the phenotypic and genotypic characterizations of the strains. Studies have indicated that the *Sporolactobacillus* species show a separate phylogenetic position and differ in phenotypic properties from the genera *Bacillus* and *Lactobacillus* (Fox et al., 1980; Ash et al., 1991; Farrow et al., 1994; Suzuki & Yamasato, 1994; Yanagida et al., 1997). According to the previous findings, the members of the genus *Sporolactobacillus* could be divided into 2 major clusters, including catalase positive and catalase negative cluster. *S. laevolacticus* is a member in the catalase positive cluster which referred to mesophilic, gram-positive, an optically pure D(-)-lactic acid-producing, motile, and spore-forming organism (Andesch et al., 1994; Chang & Stackebrandt, 2014). In the cluster of catalase-negative bacteria, the *Sporolactobacillus* species are included *S. inulinus*, *S. nakayamae* subsp. *nakayamae*, *S. nakayamae* subsp. *racemicus*, *S. terrae*, *S. kufoensis*, and *S. lactosus* (Yanagida et al., 1997). Recently, more novel *Sporolactobacillus* species have been discovered, that include *S. putidus* (Fujita et al., 2010), *S. vineae* (Chang et al., 2008), *S. pectinovorans* (Lan et al., 2016), *S. shoreicoticis* (Toleing et al., 2017), *S. shoreae*, and *S. spathodeae* (Thamacharoensuk et al., 2015).

Since these studies, the screening and isolation of the new *Sporolactobacillus* species have been successfully done. It was found that simple techniques can be applied. From various environmental resources, e.g., natural samples (soil and tree barks), spoiled foods, and feed can be heated at high temperature (~ 80°C) to eliminate the asporogeneous cells (Yanagida & Suzuki, 2009). In the enrichment step, the GYP medium containing glucose, yeast extract, peptone, and other minerals have been used for the cultivation of the isolates. For the selection, both MRS and GYP medium have been used. However, the previous study reported that the *Sporolactobacillus* species require a non-complex medium in particular GYP containing CaCO₃ medium (Chang & Stackebrandt, 2014). Until now, the phenotypic and molecular analysis of all *Sporolactobacillus* species have been clarified (Table 2). All of them are homofermentative D(-) or DL-lactic acid producer with using a variety of carbohydrates, e.g., glucose, fructose, and sucrose. Additionally, other medium components are required for growth and product formation. Most of the essential nitrogen sources, e.g., yeast extract, peptone, and inorganic nitrogen sources (NH₄Cl, NaH₂PO₄), play an important role on the concentration and productivity of lactic acid. While the free amino acids and peptides also influence in the fermentation of *Sporolactobacillus* strains, the lactic acid production might be limited by the concentration of free amino acid in the medium. The trace elements could affect lactic acid production in particular phosphate is necessary for the phosphorylation in a biological reaction which causes a significant product formation. Additionally, lactate dehydrogenase activity is induced by Mn (Klotz et al., 2017). At present, many studies have investigated using the alternative nutrition resources, e.g., protein hydrolysate from agricultural wastes for replacing the complex nutritional resources; especially yeast extract. However, lower product yield and productivity were found, compared with using yeast extract supplemented medium (Lu et al., 2009; Altaf et al., 2005).

Table 2. Differential characteristics of the *Sporolactobacillus* species*

Characteristic	1	2	3	4	5	6	7	8	9	10	11	12

*Data from Thamacharoensuk et al. (2015), Lan et al. (2016), and Tolieng et al. (2017).

Recently, the members of genus *Sporolactobacillus* have been extensively studied their performance on another application, including probiotics. Furthermore, the high efficient D(-)-lactic acid-producing *Sporolactobacillus* strains are still being explored in order to obtain the strains are able to produce high lactic acid concentration and optically pure D(-)-lactic acid for supporting the synthesis of polylactic acid (PLA) application.

The Novel Genus *Terrilactibacillus*

The novel genus *Terrilactibacillus* was firstly reported by Prasirtsak et al. (2016) in their screening and isolation of lactic acid-producing bacteria from soil samples in Thailand. The strain NK26-11^T was isolated and defined as a Gram-positive, catalase-positive, facultatively anaerobic, endospore-forming, rod-shaped, and motile by means of peritrichous flagella. The isolate showed the performance of homofermentative D(-)-lactic acid production from glucose medium. Based on its 16S rRNA gene sequence analysis, it was found that strain NK26-11^T was located between the genera *Bacillus* and *Sporolactobacillus*. *Terrilactibacillus laevilacticus* is a type species for the genus *Terrilactibacillus*. Later, during more screening and isolation on D(-)-lactic acid-producing bacteria conducted by Prasirtsak et al. (2017), *T. laevilacticus* SK5-6 as a potential D(-)-lactic acid producer was also isolated. The strain was studied the fermentation optimization in 5 L stirred fermenter using glucose medium. The results indicated that this strain could be used in industrial fermentation. Furthermore, the 2-phase fermentation approach revealed that the use of catalase-positive bacteria provides the advantage of homofermentative lactic acid production (Prasirtsak et al., 2017).

PERFORMANCE OF SPORE-FORMING LACTIC ACID BACTERIA IN VARIOUS APPLICATIONS

Lactic Acid Production

Lactic acid has long been known as a utility organic acid which can be applied in a variety of applications such as in food and non-food industries. In the field of food industry, lactic acid is well known to be used as food acidulant, preservative, flavoring, pH regulation, and mineral fortification. Lactic acid can be used as active ingredients in cosmetics industry which has the functionality as moisturizers, skin-lightening agents, humectants, anti-acne agents, and skin-rejuvenating agents (Wee et al., 2006). Considering its chemical functional groups containing a carboxylic and a hydroxy group; lactic acid can be utilized as precursors in the formulation of cleaning reagents, green solvents, and descaling agents. Moreover, lactic acid is able to be raw materials for synthesizing the useful chemicals such as propionic acid, acetic acid, acrylic acid, etc. (Dimerci et al., 1993; John et al., 2007). Currently, lactic acid is an important chemical which used as a monomer for the production of biodegradable and biocompatible polylactic acid (PLA). From the distinctive feature of PLA, it has received wide attention for utilizing in several applications, including pharmaceutical (prosthetic devices, sutures), textile (protective clothing), packaging and labeling (Wee et al., 2006; Martinez et al., 2013). Naturally, lactic acid has a chiral carbon atom which exists in two

enantiomeric forms, including L(+)-lactic acid and D(-)-lactic acid. Because its optically pure isomer affects a polymer grade of PLA; therefore, the use of optically pure isomer is more preferred than a racemic mixture of lactic acid. The recent lactic acid production is manufactured from the biotechnological process. Lactic acid bacteria (LAB) are a mandatory group as the lactic acid producer in particularly the genus *Lactobacillus*. Several advantages could be obtained from the microbial lactic acid fermentation such as high yield and productivity of lactic acid production. Moreover, the biotechnological lactic acid production provides high specificity to produce an optically pure L(+)- or D(-)-lactic acid (Pandey et al., 2001). However, the limitations and challenges of lactic acid fermentation are being continuously discussed. This includes the use of renewable resources (cellulosic sugar, food carbohydrates) as substrates, low pH inhibition, contamination due to the mesophilic characteristic of LAB strains, and decrease optical purity (Abdel-Rahman et al., 2016). Therefore, numerous researchers have studied the isolation of new microbes from natural resources and also the improvement of existing microbes by molecular technology.

Table 3. Lactic acid production by the recent strains of spore-forming bacteria

Strain	Substrate	Fermentation mode	Lactic acid				Reference
			Titler (g/L)	Yield (g/g)	Productivity (g/L·h)	%ee (Isomer)	
<i>B. coagulans</i> IPE22	Non-sterile soluble starch	SLSF ^a Batch	68.72	0.99	1.72	N/D ^b	Wang et al., 2019

<i>T. laevilacticus</i> SK5-6	Glucose	5-L Batch	92.60	0.84	1.93	99.56 (D)	Prasirtsak et al., 2017

Note: ^aOne-step simultaneous liquefaction, saccharification and fermentation.

^bThere is no report for the quantity of isomeric lactic acid purity.

Currently, SFLAB are gained attractive attention for high performance of lactic acid production with optically pure lactic acid isomer (Table 3). The genus *Bacillus* is the most used as a L(+)-lactic acid producer due to its special features compared to other genera. There are several L(+)-lactic acid fermentations using *Bacillus* strains that have been developed. Strains of *Bacillus coagulans* are reported for their remarkable L(+)-lactic acid production features, including low nutrient requirements, tolerance to high temperature and pH, strong ability to ferment both hexose and pentose sugars to high optically pure L(+)-lactic acid via pentose phosphate pathway (PPP) with 98 - 100% theoretical yield (Wang et al., 2013, 2015; Patel et al., 2006; Ye et al., 2013, 2014). The novel homofermentative *Bacillus* sp. BC-001 was firstly reported as the potent industrial L-lactate-producing strain with a high lactic acid yield (0.96 and 0.87 g/g) and productivity (2.8 and 2.6 g/L·h) using glucose and sucrose as substrates. Interestingly, the pH during L-lactic acid fermentation by the novel BC-001 could be simply controlled using monovalent bases (NH₄OH, NaOH, and KOH) (Thitiprasert et al., 2017).

According to D-lactic acid production, the wild-type *Sporolactobacillus* strains have recent been described as potential D-lactic acid producer which could produce D-lactic acid from a simple medium composition and provide a high optically pure D-lactate isomer. Additionally, the *Sporolactobacillus* species is being explored for their ability to utilize the alternative resources as substrate for D-lactic acid production. The efficient D- lactic acid production by *S. nakayamae* utilizing cheap peanut flour as a nitrogen source and commercial sucrose as a carbon source was determined. The results indicated that *S.*

According to D-lactic acid production, the wild-type *Sporolactobacillus* strains have recent been described as potential D-lactic acid producer which could produce D-lactic acid from a simple medium composition and provide a high optically pure D-lactate isomer. Additionally, the *Sporolactobacillus* species is being explored for their ability to utilize the alternative resources as substrate for D-lactic acid production. The efficient D-lactic acid production by *S. nakayamae* utilizing cheap peanut flour as a nitrogen source and commercial sucrose as a carbon source was determined. The results indicated that *S. nakayamae* is a promising new D-lactic acid producer with a high D(-)-lactic acid concentration of 112.93 g/L by fermentation using 110 g/L of sucrose, 150.40 g/L of peanut flour, and 0.16 mL/L of tween 80 (Beitel et al., 2016). Wang et al. (2011) have demonstrated the performance of *Sporolactobacillus* sp. strain CASD using various alternative nitrogen sources. It was found that a very high D-lactic acid production was achieved at a concentration of 207 g/L, the average productivity of 3.8 g/L·h and optical purity of 99.3% using 40 g/L of peanut meal in 30-L fed-batch fermentation. Compared to L-lactate yield, the production of D-lactate needs to be improved, leading to many studies that have discovered the potential strains and explored more technologies to improve D-lactate production by the strains of *Sporolactobacillus* (Nakano et al., 2018; Tolieng et al., 2017; Klotz et al., 2017; Zheng et al., 2017; Thamacharoensuk et al., 2016; Sun et al., 2015). As above mentioned, the novel genus *Terrilactibacillus* has been just discovered in a few years ago. It was found as another promising D-lactate-producing bacterium for use in industrial fermentation. *Terrilactibacillus laevilacticus* SK5-6 was screened and determined its performance of D-lactic acid fermentation using glucose medium. In this study identified *T. laevilacticus* SK5-6 as an industrial strain with 96.6 g/L final lactate titer, 0.84 g/g yield, 1.93 g/L·h, and 99.6% optical purity of D-lactate (Prasirtsak et al., 2017). The use of SFLAB members as lactic acid producers has been increasing. Because of their several advantages on providing an optically

pure lactic acid isomer and high efficiency of lactic acid production could lead SFLAB to be the lactic acid-producing candidate in future approaches.

Probiotics

The recent trend of probiotics has been extensively increasing. Probiotics are live microorganisms which identified as the beneficial microbes providing the several applications in health and clinical scenarios (Elshaghabee et al., 2017). The spore-forming lactic acid bacteria have long been explored and commercially produced as probiotics for human and animal health, in particular, *Bacillus* species (Table 4) (Khatri et al., 2016; Elshaghabee et al., 2017; Cutting, 2011; Hong et al., 2005), although a number of SFLAB information is not compared to LAB species. The findings have presented that the strains of *Bacillus* are remarked as probiotics due to their inherent ability of secretory proteins, enzymes, antimicrobial compounds, and vitamins. Various *Bacillus* lactic acid-producing species have been studied to examine their probiotic attributes. Among the *Bacillus* species, the candidate probiotic of *Bacillus* lactic acid-producing strains includes *B. subtilis*, *B. coagulans*, and *B. licheniformis*. Furthermore, the genus *Bacillus*, spore-forming lactic acid strains, is mostly recognized as the Generally Regarded As Safe (GRAS) microorganisms (Khatri et al., 2016). The distinctive endospores characteristic of the *Bacillus* species is able to resist in extreme conditions, including nutrient deprivation and environment stress (low pH, high temperatures, UV irradiation, and solvents). By their spore-forming character, the strains of *Bacillus* play a crucial role as the potential probiotic functionalities by mean of bile and acid tolerance, mucin binding, immune stimulation ability, and clinical efficacy (Khatri et al., 2016; Elshaghabee et al., 2017). Recently, several studies have reported the beneficial effect of *Bacillus* strains on the gut metabolism and physiology. Different *Bacillus* strains have shown their ability as antimicrobial, anti-oxidative and immune-modulatory in the host (Elshaghabee et al., 2017). Additionally, the *Bacillus* strains exhibit the antagonist activity which suppresses the pathogenic activities. *B. subtilis* strains were reported their antagonist activity by exhibiting aninocoumarin A activity which could attribute to the anti *H. pylori* activity (Pinchuk et al., 2001). In 2016, Gobi et al. reported the impact of *B. licheniformis* Dahb1 on reducing the formation of biofilm in the virulent *V. parahaemolyticus* Dahv2, an Asian catfish. Bacteriocin-producing strains of probiotic *B. coagulans* have been also identified. The bacteriocins of *B. subtilis* strains have a great antimicrobial activity against food-born and related clinically relevant pathogens, besides having lower cytotoxicity (Abdhul et al., 2015). Also, *B. coagulans* has been evaluated because of beneficial effect on the gut metabolism. It was indicated that feeding of *B. coagulans* to cholic acid fed rat, improved intestinal permeability and reduced the bactericidal effect of bile acid (Lee et al., 2016). Furthermore, the positive effect of *Bacillus* strains to distant cells, beyond GIT has also been established by numerous studies (Foligné et al., 2012; Abhari et al., 2016). At present, the potential probiotic *Bacillus* species are being explored for more applications. Lee et al. (2012) studied the effect of *B. subtilis* CSY191 that secretes a surfactin like compound which could inhibit the growth of anti-human breast cancer cells. Additionally, the direct effect of active compounds, which are produced by the *Bacillus* species have been determined as the alternative and effective therapy for metabolic syndromes (Choi et al., 2016; Yang et al., 2014; Ghoneim et al., 2016;

Zouari et al., 2015). Commercially, the probiotic products are under regulated, depending on the regulatory system of the country. In terms of the *Bacillus* lactic acid-producing strains, these are one of the mostly commonly used as probiotic based products in the range of human health supplements, animal feed, and aquaculture (Elshaghabee et al., 2017).

Table 4. Probiotics of spore-forming LAB in the worldwide market

Strain and description	Probiotics	Target
<i>B. licheniformis</i> (NCTC 13123) at 10^9 - 10^{10} spores/kg, non-bacteriocin strain and not licensed in the EU.	AlCare™	Swine
<i>B. licheniformis</i> (1.6×10^9 CFU/g) and <i>B. subtilis</i> (1.6×10^9 CFU/g).	BioGrow®	Poultry, calves and swine
Mixture (1/1) of <i>B. licheniformis</i> (DSM 5749) and <i>B. subtilis</i> (DSM 5750) at (1.6×10^9 CFU/g) of each bacterium. EU approved.	BioPlus 2B®	Piglets, chickens, turkeys for fattening
Carries 4 strains of <i>B. subtilis</i>	Promarine®	Aquaculture shrimps
<i>B. coagulans</i> (1.0×10^9 spores/dose)	Lactopure	Poultry, swine, calves
<i>B. coagulans</i> and <i>B. subtilis</i>	NutriCommit	Human
<i>B. coagulans</i> (1.0×10^9 spores/dose)	Lactospore	Human
<i>B. coagulans</i> GBI-30	Sustenex	Human
<i>B. coagulans</i>	Neolactoflorene	Human
<i>B. coagulans</i> 15B and fructooligosaccharide	Nutrition essentials Probiotic	Human
Labelled as dietary supplement contained a stable <i>B. coagulans</i> that survives in stomach acid and retains its potency in the intestines.	THORNE®	Human
<i>B. coagulans</i> (<i>B. coagulans</i> GBI-30, 6086)	GanedenBC ³⁰	Human and animal

*Information was modified from Cutting (2011), Elshaghabee et al. (2017), Konuray and Erginkaya (2018), and Hong et al. (2005).

The spore former *Sporolactobacillus* species have been also studied as probiotics. However, only a few studies have worked on the function of probiotic *Sporolactobacillus* species. Hyrominus et al. (2000) studied the performance of various *Sporolactobacillus* strains for being as probiotics by testing their acid and bile tolerance in different cultivations. The study reported that the examined *Sporolactobacillus* strains could survive in acidic conditions (pH 2.5 - 3) and some are weakly tolerant to 0.3% bile. Moreover, the study suggested that other parameters such as the spore-forming behavior in the gastrointestinal tract should be considered. The basic characteristics of *S. inulinus* BCRC 14647 were determined for its potential probiotic properties. Several factors, including acid and bile tolerance, adhesiveness, and antagonistic effects on pathogenic *Salmonella enteritidis* BCRC 10744 were tested. The results revealed that the vegetative cell form of *S. inulinus* exhibits probiotic features (Huang et al., 2007). The draft genome sequence of *S. vineae* SL153^T was analyzed to determine its probiotic characteristics. The study found that *S. vineae* SL153^T presents a high level of cell adhesion activity and growth inhibitory effect on pathogenic bacteria, including *Vibrio cholerae*, *Vibrio alginolyticus*, *Vibrio fluvialis*, *Vibrio parahaemolyticus*, *Aeromonas bivalvium*, *Listonella anguillarum* which improves the effectiveness of the prevention and treatment of disease infected by these pathogenic microorganisms (Kim et al., 2012).

Several numbers of researches have been developing in both phenotypic and genotypic probiotics in order to achieve the greatly beneficial human and animal health. Thereby, in

order to promote health benefits, suitable probiotic formulations should be considered. Furthermore, a little information on probiotics spore-forming bacteria for clinical trial testing has been revealed. It is noted that further studies on the functionality and safety of probiotic spore-forming bacteria are required.

Other Applications and Future Perspectives

SFLAB, especially the *Bacillus* strains, have long been considered as the cell factories for the production of significant substances. Enzyme technology is one of the most important application that could be obtained from SFLAB. Various extracellular enzymes are commercially produced by *B. subtilis*, *B. licheniformis*, and *B. coagulans*. Moreover, most of enzymes produced by *Bacillus* strains have been used as thermostable enzymes (Friszte & Claus, 1995). Bacterial enzymes including amylase, pullulanase, xylanase, lipase, proteinase, α -glucosidase, cyclodextrin glycosyltransferase, glucose isomerase, 1,4- β -galactosidase, protease, DNA polymerase and restrict endonucleases have been used by food, pharmaceutical, textile, cosmetic, and household detergents industry (Meima et al., 2004; Kumar et al., 2005; Kanwar et al., 2006).

As previously mentioned for probiotics, SFLAB strains have the ability to produce antimicrobial substances against different food-borne pathogens, such as *Salmonella typhimurium*, *Clostridium perfringens*, and *Escherichia coli* (Shivaramaiah et al., 2011; Tactacan et al., 2013; La et al., 2001). Additionally, *Bacillus* strains are also the commercial product in the field of agriculture. *Bacillus subtilis* has been found as a promotor of plant growth by improving the survival and robustness of the seedlings (Cavaglieri et al., 2005; Ugoji et al., 2005).

Nowadays, the trend of healthy and functional food is widely interesting. Probiotic SFLAB have been extensively explored. However, compared with LAB, the lactic acid spore formers have not gained high popularity yet. Thereby, there is a need to elucidate and evaluate the features of spore former probiotic strain. Moreover, the association of safety and licensing issues that influence the use of bacteria spore former should be clarified. In addition to improve the polymer grade, SFLAB is presented as a good lactic acid producer which provide a high product yield and the desired stereoisomer, optically pure L(+)- or D(-)-lactic acid. So far, a stable and highly productive lactic acid fermentation is required. Therefore, the potential of SFLAB should be further explored. Furthermore, the cost reduction of biotechnological lactic acid production is now being developed.

CONCLUSION

SFLAB have been gaining attractiveness as microorganisms because of their many efficacies utilized in many applications. The endospore-forming characteristic provides an excellent ability of SFLAB to tolerate extreme conditions (like high temperature, pH, salts, and reagents). Interestingly, SFLAB has resilient features, for instance, the SFLAB strains could grow and produce product either under aerobic or facultative anaerobic condition, including the use of alternative resources as a substrate. Thereby, SFLAB have become an

attractive outcome for being lactic acid-producing candidate and probiotics. Additionally, SFLAB are able to be the enzymes factory which produce variety of enzymes. Furthermore, most of these SFLAB enzymes are now applied in various industries. Nonetheless, there is a little information regarding SFLAB; therefore, it is necessary to develop more studies for understanding SFLAB features.

Chapter 305

PUBLIC HEALTH SIGNIFICANCE OF FRINGILLIDAE: VIRAL, BACTERIAL, MYCOTIC, PARASITIC AND ALLERGENIC APPROACHES

Hadi Tavakkoli

Department of Clinical Science, School of Veterinary Medicine,
Shahid Bahonar University of Kerman, Kerman, Iran

ABSTRACT

Finches are the most popularly kept passerine species within aviculture. The zoonotic diseases of Fringillidae have always been a major concern for owners. Various *viral, bacterial, fungal, parasitic and* allergenic agents of Aves are able to transmit to humans. In the present chapter, emphasis will be placed on the significance of each of the mentioned agents for public health. The subheading will exist on specific subjects such as the etiology of the disease; epidemiology, economic significance, public health significance, transmission, clinical signs, diagnostic procedures and principle of disease prevention thus making the owners aware of the serious threat of finches.

INTRODUCTION

Zoonoses refer to infectious animal diseases that are communicable to humans. Avian and humans have different physiologies, and consequently, most avian diseases do not pose a serious threat, but owners should be aware that some avian diseases transmit to humans. Many zoonotic diseases can be prevented by understanding basic disease transmission principles and the criteria of preventive practices.

Infectious organisms are transmitted by five categories including zoonoses: the pathogen is transmitted via direct or indirect contact, and does not pass through the life cycle; saprozoonosis: spread by the alimentary tract; metazoonosis: by biological and mechanical vectors; cyclozoonosis: vertebrates are intermediate hosts and xenozoonosis: by transplantation of organs from infected animals. Individual susceptibility and the seriousness of zoonotic disease varies with age, health status, immune status (immunodeficient or immunosuppressed), virulence of the organism, the dose to which the person is exposed, the duration of exposure as well as route of infection.

The order Passeriformes contains over 5700 species. The most common representatives of the passerines in captivity are finches. This chapter primarily covers zoonotic diseases that occur in passerine birds. It should be expected that the zoonotic disease in finches is similar to other passerines and the disease characteristics, transmission, and diagnosis are essentially the same. If evidence of variations is mentioned in literatures, it will be described.

Infections of passerines with zoonotic pathogens can be grouped into 5 categories, each of which is the subject of a separate section of this chapter. The first section discusses infections with the viral pathogens such as arboviral infections, orthomyxovirus type A and avian paramyxovirus type 1, which generally have a worldwide distribution. Arbovirus is referred to viruses that transmit to vertebrates by the bite of arthropod vectors such as mosquitoes, flies, and ticks. Various arboviruses are able to cause disease in humans. However, the discussion here will be limited to 2 that are reported in both humans and finches: Eastern equine encephalitis virus and West Nile virus. The second section of this chapter discusses infections with the numerous bacteria. These bacterial diseases, include, arizonosis, campylobacteriosis, chlamydiosis, colibacillosis, erysipelas, listeriosis, tuberculosis, salmonellosis, staphylococcosis and yersiniosis. The third section discusses infections with fungi pathogens. Fungal infections are a significant problem in Fringillidae. The first focus is cryptococcosis, followed by other infections. Cryptococcosis is one of the most prevalent mycosis of birds. Dermatophytosis is the principal fungal infection of the keratinized areas of the body, including the hair, nails, and skin. Dermatophytosis was reported in passerines and is notable as a public health hazard. Histoplasmosis and microsporidiosis are associated with a wide spectrum of clinical illness, especially in human. Avian mite dermatitis and toxoplasmosis have been detected in passerines and these are described in the fourth section of this chapter. These zoonoses are caused by parasitic organisms. The final section of this chapter discusses zoonoses due to allergenic agents. Allergic alveolitis, which is connected with the allergens in bird feathers, droppings, epithelium or fecal dust, also merits mention.

Diseases are presented alphabetically within categories defined by the type of infectious agent (i.e., viral, bacterial, fungal, parasitic and allergenic). For each disease, there is a subheading on specific subjects such as the etiology of the disease, epidemiology, economic significance, public health significance, transmission, clinical signs, diagnostic procedures and principle of disease prevention.

SECTION 1: VIRAL DISEASES

Eastern Equine Encephalitis

Etiology and Organism Biology

Eastern equine encephalitis virus causes eastern equine encephalitis. The disease is an arbovirus infection. Arbovirus is a generic term referring to viruses transmitted to vertebrates by the bite of arthropod vectors.

Epidemiology

Many outbreaks of eastern equine encephalitis were reported in pheasants and chukar partridges flocks, but it usually occurs sporadically in other birds. The disease is found in some areas such as North and South America. Eastern equine encephalitis outbreak often occurs in late summer and fall following increasing numbers of mosquito vectors. Outbreak of eastern equine encephalitis has been reported in finches [1, 2].

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Clinical manifestations of human infection with eastern equine encephalitis virus are flu-like disease with fever, headache, and fatigue. Some patients exhibit neurological signs, including meningitis or encephalitis. Recovery can take several weeks to a few months. The major mode of transmission to human is from the bite of an infected arthropod vector. The primary enzootic transmission cycle occurs between birds and mosquitoes.

Hosts

Outbreaks of eastern equine encephalitis have been reported in various avian species, including pheasants [3], pigeons [4], chukar partridges [5, 6], turkeys [7, 8], ducks [9] and finches [1, 2, 10].

Transmission, Carriers, Vectors, Spread

- 1) Vectors of eastern equine encephalitis virus are ornithophilic mosquito (*Culiseta melanura*), *Culicoides*, *Aedes sollicitans*, *Coquilletia perturbans*, *Culex melanura*, *Culex pancossa*, *Culex dunni*, *Culex sacchettae*, simuliid flies, mites and lice [11, 12]. Transmission to mammalian species can occur by mosquitoes such as *Aedes* spp. and *Coquilletia* spp.
- 2) In some birds, transmission occurs following feather picking, cannibalism, and oral inoculation [13]. Transmission of virus by semen also has been reported [14].
- 3) Passeriformes are the principal vertebrate hosts of eastern equine encephalitis virus [15, 16]. These birds rarely become ill but serve as maintenance and amplifying hosts for the virus.

Incubation Period

In experimental studies, many wild birds were found to have viremia lasting up to 4 days [16].

Clinical Signs

Clinical disease produced by eastern equine encephalitis virus in finch is usually attributed to central nervous system infection (paresis) with or without involvement of viscera. Death is also demonstrated to occur [1, 2].

Diagnostic Procedures

The diagnosis of eastern equine encephalitis disease is based on clinical symptoms, histopathological examination, virus isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Detection of viral RNA by molecular techniques such as RT-PCR [17].
- 2) Detection of viral antigens by antigen-capture ELISAs [18, 19], or immunohistochemistry [20].
- 3) Serologic testing [21].
- 4) Isolation requires inoculation of blood or tissue (brain, spleen, liver, heart) into cell cultures, embryonated chicken eggs or mice.

Prevention

The following criteria should be considered to prevent and control the eastern equine encephalitis.

1) Biosecurity

Biosecurity keeps the disease from entering into the finch facility. Prevention of eastern equine encephalitis is associated with measures aimed at reducing vector populations. If practicable, aviaries should be located away from wetlands and other areas that are habitats for vectors.

2) Vaccination

No commercial vaccine is licensed for prevention of eastern equine encephalitis in finches.

West Nile Viral Encephalitis

Etiology and Organism Biology

West Nile virus is an arthropod-borne virus (arbovirus) in the family Flaviviridae, genus *Flavivirus*. Flaviviruses are single-stranded, positive-sense, enveloped RNA viruses with icosahedral nucleocapsid symmetry.

Epidemiology

West Nile virus has been described in Africa, Europe, the Middle East, West and Central Asia, Oceania and in the Western Hemisphere.

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Infection usually occurs as a result of a mosquito bite while taking blood. Non-arthropod-borne routes of transmission have been reported. These transmission routes in humans include infection through contaminated organ transplantation, blood transfusion, vertical transmission by breast milk and intrauterine transmission and occupational exposure through laboratory [22, 23].

Hosts

West Nile virus has also been reported in Passeriformes and finches [24-27].

Transmission, Carriers, Vectors, Spread

- 1) Transmission occurs between susceptible vertebrate hosts by blood-feeding arthropod mosquitoes, sand flies, ceratopogonids, and ticks [27-31].
- 2) Experimentally, infection has been reported following oral exposure in cats fed infected birds [32, 33].
- 3) Fecal shedding was identified as a potential route of transmission between bird aviaries [24, 34].
- 4) Birds are the natural reservoir species, they may act as dead-end hosts or viral amplifiers [23].
- 5) Human and domestic animals may show clinical signs, but often are incidental or “dead-end” hosts because they do not exhibit significant viremia and do not contribute to the transmission cycle.

Clinical Signs

Infected birds in North America have a spectrum of clinical outcomes ranging from no disease to death [23]. In most species of birds, common clinical signs include depression, recumbency, anorexia, weight loss and death, with no previous clinical signs of illness. Neurologic signs (disorientation, ataxia, circling, abnormal head posture, tremors, impaired vision,) have also been reported [26, 35-40].

Diagnostic Procedures

The diagnosis of disease is based on clinical symptoms, histopathological examination, virus isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Detection of viral genome by molecular technique such as PCR.
- 2) Detection of viral antigens by antigen-capture ELISAs or immunohistochemistry in tissue, blood, CSF, or other body fluid [23].
- 3) Hematologic abnormalities such as leukocytosis and heterophilia, infrequent monocytosis and reactive lymphocytes were reported in some species [35, 38, 41].

Prevention

The following criteria should be considered to prevent and control the infection.

1) Biosecurity

Biosecurity keeps the disease from entering into the finch facility. Prevention of disease is associated with measures aimed at reducing vectors such as mosquitoes, sand flies, ceratopogonids, and ticks.

The virus may also be transmitted through contact with infected animals, birds, their blood, or other tissues. Thus, laboratory and clinical workers as well as owners who handle infected birds, tissues or fluids are at risk of virus exposure. To minimize risk, persons should have appropriate personal protective equipment such as gloves, gowns and masks. Owners must wash hands and other skin surfaces with soap and water immediately after contact with infected birds and contaminated materials.

2) Vaccination

No commercial vaccine is licensed for prevention of eastern equine encephalitis in finches.

Influenza

Etiology and Organism Biology

Influenza is described as an infection of avian caused by Type A influenza. The influenza viruses are classified in family *Orthomyxoviridae* genus *Influenzavirus* A. The severe and lethal disease caused by influenza viruses is referred to as “highly pathogenic avian influenza” or HPAI. Milder forms of influenza have been named “low pathogenic” or “non-highly pathogenic” avian influenza (LPAI). The World Organization for Animal Health (OIE) suggests the terms “highly pathogenic notifiable avian influenza (HPNAI) and “low pathogenic notifiable avian influenza (LPNAI)” for influenza viruses[42].

Virions lengths are about 120 nm with spherical, pleomorphic or filamentous shape. Two types of glycoprotein projections are located on the viral surface: (1) hemagglutinin (HA) which are rod-shaped trimers and (2) neuraminidase (NA) which are mushroom-shaped tetramers. The viral genome includes eight segments of single-stranded, negative-sense RNA and codes 10 or 11 proteins as follows: (1) Eight structural protein (HA, NA, NP, M1, M2, PB1, PB2, and HA), and (2) nonstructural protein (NS1 and NS2) (NS1). Type A influenza viruses are subtyped based on sequence analysis of HA and NA genes or serologic reactions of the HA and NA surface glycoproteins. Eighteen subtypes of HA (H1-18) and eleven subtypes of NA (N1-11) are recognized for avian influenza viruses.

Epidemiology

Avian influenza viruses have a worldwide distribution and infections with influenza virus have been reported in many avian species [43-50]. Unfortunately, in most areas of the world, the type of influenza virus subtypes currently circulating among finches is not clearly defined.

Economic Significance

Passerines diseases have a significant impact on human welfare, especially in areas where finches rearing is a source of income. Owners also expend large amounts of money to prevent influenza, to maintain an influenza-free aviary, or control disease after an outbreak.

Public Health Significance

Influenza viruses possess host species adaptation, but interspecies transmission of avian influenza to humans has been reported. Interspecies transmission may occur via (1) transmission of complete virions and (2) transmission of viral gene segments. The H5 or H7 HPAI viruses are important among avian influenza viruses and have more public health significance than all the other influenza viruses.

Clinical manifestations of human infections with AI viruses vary from mild to severe and depend on the subtype. The H7 subtype has mainly been associated with conjunctivitis and mild influenza-like illness, whereas H5N1 viruses have been associated with more severe respiratory disease. Clinical manifestations of human infections with avian influenza include fever, dyspnea, pneumonia, cough, myalgia and gastrointestinal signs [51, 52].

Hosts

Avian influenza viruses have been demonstrated to infect a wide variety of wild and domestic birds [50, 53-59]. Therefore, it is concluded that almost all finches are susceptible to infection, at least until further data are provided on resistance for specific species.

Transmission, Carriers, Vectors, Spread

- 1) In various species of birds, avian influenza viruses replicate in the respiratory, intestinal, renal, reproductive and epidermis (including feather follicles for HPAI viruses) and are shed from the nares, mouth, conjunctiva, and cloaca of infected birds into the environment. In this regard, Tavakkoli et al. [60] assessed the excretion time of H9N2 avian influenza subtype in zebra finch. H9N2 avian influenza subtype was shed in tracheal and cloacal swabs of the infected finches, three and five days post inoculation, respectively. The maximum virus titer in tracheal and cloacal swabs was detected on days 2 and 3 post inoculation. In comparison to the trachea, the virus was recovered in cloaca for a longer time.
- 2) The virus is transmitted by direct contact between infected and susceptible birds or indirect contact through aerosol droplets or exposure to contaminated fomites.
- 3) Avian influenza viruses are readily transported to aviaries by human (contaminated shoes and clothing), wild bird, imported birds and contaminated equipment.

Incubation Period

The incubation period for the avian influenza viruses is various and ranges from as little as a few hours for HPAI subtype to several days in birds. The incubation period depends on the various factors such as the dose of the virus, the age of exposure, etc.

Clinical Signs

The virulence of avian influenza virus (LPAI or HPAI) has a critical impact on the clinical outcome of the disease. However, clinical signs of influenza are variable and depend

on many factors, including host immunity, age, sex, environmental factors and concurrent infections.

In companion birds, it is reported that the influenza causes non-specific signs. The disease can cause mortality in birds within several days of infection. Depression and neurologic signs may present. These signs include attenuated motor functions, such as paresis to paralysis, vestibular dysfunction as indicated by torticollis and nystagmus, and general behavior aberrations such as loss of balance. Following intranasal inoculation of H9N2 virus, the zebra showed clinical signs including decreased activity, lethargy, ruffled feathers and decreased feed consumption. The course of the disease was three to five days [60]. Damage of Zebrafish skeletal muscle was also reported following influenza A Virus Infection [50].

Diagnostic Procedures

It can be especially difficult to recognize the disease due to variable and non-specific clinical signs. The diagnosis of influenza disease is based on clinical symptoms, histopathological examination, virus isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Molecular techniques such as RT-PCR and RRT-PCR. These assays detect viral RNA in swab samples or tissues.
- 2) Immunohistochemistry, immunocytochemistry, and immuno-fluorescent techniques. These assays detect the specific locations of the viral antigens in tissues or cells.
- 3) Serologic techniques such as agar gel immunodiffusion (AGID), ELISA and HI. These assays detect and quantify antibodies to influenza virus. AGID detects anti-NP antibody to all influenza A viruses.

ELISA assay detects antibodies to AI viruses. If the ELISA kit were available for finches, it would be useful for testing the finch's sera, but that specific kit is not always available. HI assay detects antibodies to the HA antigene of the influenza virus. The HI test cannot differentiate antibodies induced from an infection with influenza virus or those induced by vaccination with commercial vaccines. The sera of many passerines may contain nonspecific inhibitors and cause problems in HI assay. Therefore, sera should be treated to decrease or destroy such inhibitors. The two techniques used for these inhibitors are receptor destroying enzyme (RDE) and potassium-periodate. In addition, chicken red blood cells are usually used in HI tests. Caution should be taken when using sera from species other than chickens (such as finches) in the HI test because they may cause false positives due to nonspecific agglutination. So, the pre-treatment procedure is needed prior to HI test. This problem may also be avoided by using erythrocytes in the HI test of the same species. Attention should be paid to the OIE approved protocol to avoid variations in results from different laboratories [61, 62].

Prevention

The following criteria should be considered to prevent and control the influenza disease.

1) Biosecurity

Biosecurity keeps the disease from entering into the finch facility and prevents susceptible finches from infection. So each method of disease transmission and spread must be noticed in this policy.

2) Disinfection

It is critical that organic matter be removed before the disinfection protocol. Physical conditions such as dryness, heat and extremes of pH can inactivate avian influenza viruses. Avian influenza viruses have lipid envelopes and they are destroyed by detergents. Commercial disinfectants such as phenol, quaternary ammonium and sodium hypochlorite will inactivate influenza viruses.

3) Vaccination

Vaccination reduces the number of susceptible birds, decreases morbidity, mortality and viral shedding into the environment [63-66]. The most frequently licensed influenza vaccine in most countries is inactivated vaccine for LPAI. However, protection is virus subtype specific. Birds are susceptible to all of the HA subtypes, and there is no way to predict their infection to any particular subtype. Therefore, it is not practical to use preventive vaccination against all influenza subtypes. However, if a particular HA subtype is at risk in a certain area, vaccination can be a useful tool in a control program. Unfortunately, at this time there are no substantive data about certain HA subtypes, which are circulating in finches in most parts of the world.

Inactivated vaccines are given intramuscularly or subcutaneously. They are often mixed with other vaccines as a multivalent product to decrease the cost of administration. Vaccination programs may be arranged by veterinarian policies in each area and depend on the status of the disease in the region, maternal immunity, the quality of biosecurity, available vaccines, use of other vaccines and cost. Some owners have a regulated program for vaccination. Based on the author's experience, it is useful for finches to receive at least 2 inactivated LPAI influenza vaccines over the year in the areas where the LPAI influenza is endemic. Additional considerations that influence the decision on vaccination for HPAI are based on the government program. Because differentiating vaccinated from infected (DIVA) strategies does not exist for influenza in many finch aviaries, it is difficult to discern infected from vaccinated birds.

Newcastle Disease

Etiology and Organism Biology

The virus family Paramyxoviridae is classified in order Mononegavirales that is a single-stranded, nonsegmented, negative-sense, enveloped RNA virus with helical capsid symmetry. Eleven serotypes of avian paramyxoviruses (APMV) have been recognized: APMV-1 to APMV-11. Of these, APMV-1 remains the most important pathogen for passerines. APMV-2 and APMV-3 are also isolated from passerines with no public health significance.

Newcastle disease is described as an infection of avian caused by avian APMV-1. The disease is caused by infections with virulent isolates of APMV-1 that meet one of the following aspects for virulence:

- 1) By an intracerebral pathogenicity index (ICPI) in day-old chickens (*Gallus gallus*) of 0.7 or greater.
- 2) Demonstration of multiple basic amino acids in the virus genome at the C-terminus of the F2 protein and a phenylalanine at residue 117, which is the N-terminus of the F1 protein.

Epidemiology

There are few regions in the globe, which have not been affected by Newcastle disease viruses. Newcastle disease is particularly problematic for finches reared in close proximity to other avian species. The spread of Newcastle disease virus between various countries including Asia, the Middle East, Europe, and Africa has also been documented [67]. Unfortunately, in most areas of the world, the type of Newcastle disease virus strain or genotypes that are currently circulating among finches is not clearly defined.

Economic Significance

Finch diseases have a significant impact on human welfare, especially in areas where finches rearing is a source of income. Owners also expend large amounts of money to prevent Newcastle disease, to maintain a Newcastle disease-free aviary, or eradicate disease after an outbreak.

Public Health Significance

The isolation of Newcastle disease virus from humans is rare; however, when it does arise it is often isolated from those who have close contact with passerines, or have an infection from live vaccines during vaccination, or acquired from laboratory infections. The recovery will happen in 7–20 days. Following direct contact of the eye with infective fluids or aerosols, a self-limiting conjunctivitis without involvement of the cornea was reported. Furthermore, after ocular contamination, in humans flu-like symptoms may occur. Intravenous inoculation of the Newcastle disease virus in humans led to general malaise, neutropenia, leucopenia, thrombocytopenia and flu-like symptoms. However, risk factors such as immunosuppression in human may increase the possibility of Newcastle infection and severe pneumonia. There are no reports of human-to-human transmission [68, 69].

Hosts

Newcastle disease has been documented in at least 241 species [70-74] (150). Therefore, it is concluded that almost all finches are susceptible to infection at least until further data are provided on resistance for specific species.

Transmission, Carriers, Vectors, Spread

- 1) The principal mode of viral transmission is horizontal through respiratory, fecal and oral secretions. Infected birds shed Newcastle disease virus in oropharyngeal and

fecal secretions. Finches may also become infected by inhaling contaminated dust or aerosolized virus or by ingesting such material.

- 2) It is difficult to prove vertical transmission of Newcastle disease virus from parent to offspring, but it is reported in some references [75]. Hatchling birds may be infected by contact with contaminated feces through eggshell cracks or by exposure to a contaminated environment.
- 3) Vaccinated birds can shed the Newcastle disease virus for several days and are the sources of viruses to other susceptible birds. For example, immunized chickens shed Newcastle disease virus for 6–9 days after challenge [76]. Parrots, cormorants, and pigeons have longer time of Newcastle disease virus shedding, usually in feces, without clinical signs [77-79]. Based on these results it is concluded that the vaccinated finches can shed and spread the virus in the environment/or to healthy finches; but the time of shedding is not clearly defined and needs further study.
- 4) The infected birds can be carriers for months before the clinical symptoms become manifest.
- 5) The virus can be spread by humans through transport of contaminated fomites.
- 6) Mechanical vectors (equipment, clothing, shoes, feed, water, infected avian products) may spread the virus.
- 7) Wild or domestic infected birds that are moved or placed into contact with susceptible finches may lead to the spread of Newcastle disease virus through inhalation or ingestion.
- 8) Migratory birds have been suggested in the introduction of the disease in certain areas.
- 9) Two different fly species can carry Newcastle disease virus. Flies can be considered competent vectors [80].

Incubation Period

The incubation period may be between 3 and 28 days depending on the age of the bird, immune status of the bird, the virulence of the virus and the dosage of the virus.

Clinical Signs

Clinical signs of infected birds vary depending on the virulence and the dosage of the infecting virus, the immune status and age of the finches as well as environmental conditions. In passerines, APMV-1 may result in sudden death. Clinical signs can involve the CNS (head shaking, head tremors, head tilt, circling, paralysis, ataxia, twisted neck, opisthotonos, torticollis), respiratory (conjunctivitis, nasal discharge), gastrointestinal (diarrhea, melena, intestinal hemorrhage) and urogenital (polyuria, drop in egg production) systems. General signs such as depression and varying degrees of weight loss were also noted. Some infected birds may survive for up to several months after developing CNS signs.

Diagnostic Procedures

It can be especially difficult to recognize the disease due to various clinical signs of infected birds. The diagnosis of Newcastle disease is based on clinical symptoms, histopathological examination, virus isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Molecular techniques such as RT-PCR and RRT-PCR. These assays detect viral RNA in swab samples or tissues.
- 2) Immunohistochemistry, immunocytochemistry, and immuno-fluorescent techniques. These assays detect the specific locations of the viral antigens in tissues or cells.
- 3) Serologic techniques such as ELISA and HI. These assays detect and quantify antibodies to Newcastle disease virus. ELISA is usually specific for the host species. If the ELISA kit were available for finches, it would be useful for testing the finch's sera, but that specific kit is not always available. HI assay detects antibodies to only the HN gene of the Newcastle disease virus. The HI test cannot differentiate antibodies induced from an infection with Newcastle disease virus or those induced by vaccination with commercial vaccines. Chicken red blood cells usually are used in HI tests. Caution should be taken when using sera from species other than chickens (such as finches) in the HI test because they may cause false positives due to nonspecific agglutination [81]. So, the pre-treatment procedure is needed prior to HI test. Attention should be paid to the OIE approved protocol to avoid variations in results from different laboratories[82]. When applying 4 HA or 8 HA units of antigen, titers greater than 1:16 or 1:8 are considered positive, respectively.

Prevention

The following criteria should be considered to prevent and control the Newcastle disease.

- 1) **Biosecurity**

Biosecurity keeps the disease from entering into the finch facility and prevents susceptible finches from infection. So each method of disease transmission and spread must be noticed in this policy.

- 2) **Disinfection**

It is critical that organic matter be removed before the disinfection protocol. Commercial disinfectant such as phenol and quaternary ammonium will inactivate Newcastle disease viruses.

- 3) **Vaccination**

Vaccination reduces the number of susceptible birds, decreases morbidity, mortality and viral shedding into the environment. Two types of commercial vaccines are available in most countries: inactivated and live vaccines. Strains of low virulence, such as B1 and LaSota, are the most common vaccine strain. Other strains such as Ulster, QV4, I-2 and VG/GA are also commercially used especially in chicken farms. Live vaccines can be administered by various methods, but ocular delivery provides the best response compared to drinking water or spray. Inactivated vaccines are given intramuscularly or subcutaneously. Inactivated vaccines produce high neutralizing antibody levels and they are less affected by maternal antibodies. They are often mixed with other vaccines as a multivalent product to decrease the cost of administration.

Vaccination programs may be arranged by veterinarian policies in each area and depend on the status of the disease in the region, maternal immunity, the quality of biosecurity, available vaccines, use of other vaccines and cost. Some owners have a

regulated program for vaccination. Based on the author's experience, it is useful for finches to receive at least 3 live vaccines with 2 inactivated over the year in the areas where the Newcastle disease is endemic. Because differentiating vaccinated from infected (DIVA) strategies does not exist for Newcastle disease in many finch aviaries, it is difficult to discern infected from vaccinated birds.

SECTION 2: BACTERIAL DISEASES

Arizonosis

Etiology and Organism Biology

Arizonosis is a septicemic disease of birds caused by the bacterium *Salmonella enterica* subsp. *Arizonae*. The organism is Gram-negative nonsporogenic bacilli that are motile by flagella.

Epidemiology

Avian arizonosis occurs worldwide.

Economic Significance

Avian arizonosis has considerable economic significance for the pet bird owners through increased mortality in birds and affected egg production in breeders and decreased hatchability. Cost is incurred in testing carrier birds, cleaning and disinfection, treatment of affected birds and preventing the disease.

Public Health Significance

In humans, diarrhea is the most common symptom. Many infections are subclinical. Septicemia can occur in immunocompromised individuals.

Hosts

Many species of avian, mammalian, and reptilian are susceptible.

Transmission, Carriers, Vectors, Spread

- 1) Infected birds are intestinal carriers and spreaders of *Salmonella entericaarizonae* for long periods.
- 2) Wild birds, rats, mice, and reptiles are common sources of the organisms for aviaries.
- 3) Transmission is by the fecal-oral route.
- 4) Transmission of the organism through eggs has been reported in some birds.
- 5) *Salmonella entericaarizonae* is transmitted in the incubator by direct contact. The organism can also transmit through contaminated feed and water.

Incubation Period

In general, the incubation period of the disease in birds is 6-72 hours, although 12-36 hours is most common, but it is not clearly defined in finches.

Clinical Signs

In most birds, infection results in weakness, anorexia, mortality, reduced egg production and hatchability.

Diagnostic Procedures

The diagnosis of arizonosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

The organisms may be recovered from affected tissues, including liver, spleen, heart, blood, intestine, lung, kidney and brain.

Prevention

The following criteria should be considered to prevent and control the arizonosis.

1) **Biosecurity**

Finch aviary can be contaminated with *Salmonella* in many different ways. So each method of disease transmission and spread must be noticed in this policy.

2) **Disinfection**

Salmonella entericaarizonae are readily destroyed by heat and common disinfectants.

Campylobacteriosis

Etiology and Organism Biology

The genus campylobacter contains 18 species, with *Campylobacter fetus* being the type species. They are thermophilic and Gram-negative bacteria. The most frequent and apathogenic *Campylobacter* spp. in passerines is *Campylobacter fetus* subsp. *jejuni*. There are at least 50 serovars of *Campylobacter jejuni*. *Campylobacter Coli* is also isolated from birds, but is considered to be apathogenic. *Campylobacter jejuni* and *Campylobacter Coli* reside in the intestinal tract of birds.

Epidemiology

Campylobacter jejuni has a worldwide distribution [83-85]. Outbreaks of campylobacteriosis have been reported in finches [86, 87].

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Most human infections are caused by the *Campylobacter jejuni* and *Campylobacter Coli*. Clinical manifestations of human infection, include fever, abdominal pain and profuse or bloody diarrhea. Transmission occurs by ingestion of the organisms.

Hosts

The host spectrum is large and includes chickens, pheasants, turkeys, gulls, ducks, geese, crows, pigeons, Pekin nightingale, shorebirds, nandu, Great bustard, Psittaciformes and canaries. *Campylobacter jejuni* is often found in tropical finches, especially in Estrildidae.

Transmission, Carriers, Vectors, Spread

- 1) Horizontal transmission from the environment to finch's aviaries is an important mode of transmission.
- 2) Potential sources of infection for birds include feces, contaminated or unchlorinated water and equipment, farm animals (pigs, cattle, and sheep), domestic pets, wildlife birds and maybe owners.
- 3) In some species, vertical transmission of campylobacter was suggested but few documented cases have been reported in passerines [88].
- 4) Society or Bengalese Finches (*Lonchura domestica*) can be carriers without conspicuous clinical symptoms [83]. But, when they are used as foster parents for finch chicks, the chicks suffer.
Insects (houseflies, cockroaches, mealworms, etc.) can act as mechanical vectors.
- 5) Rodents and raccoons harbor campylobacter in their intestines, and thus animals can potentially introduce campylobacter to aviaries.
- 6) Dogs can be a reservoir for human infections, but it is not clear if they can transmit the organisms to birds. Therefore, dogs should not be allowed direct access to finch's house.
- 7) *Campylobacter jejuni* can be shed from the intestinal tract of clinically affected and asymptomatic birds.

Incubation Period

The incubation period of campylobacter is not clearly defined in finches. But, in other avian species *campylobacter* colonization could occur as early as one day after inoculation [89-91].

Clinical Signs

Clinical signs include apathy, emaciation, yellow droppings, retarded moulting and high mortality, especially among fledglings. The yellow droppings contain large amounts of amylum (undigested suspension). Sometimes parts of or whole seeds are seen in the droppings. The disease has been associated with the production of pale voluminous droppings and nestling mortality [86]. The pale fecal color is due to the presence of undigested starch. Sudden death due to liver rupture is possible. Finches can also be carriers without conspicuous clinical symptoms [83]. The disease frequently occurs in birds with parasitic infections (coccidia and nematodes), and these agents have been suggested as predisposing factors.

Diagnostic Procedures

The diagnosis of *campylobacteriosis* is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) The diagnosis is confirmed by demonstrating the bacteria in smears from the droppings, affected tissues or gut contents. *Campylobacter jejuni* may appear in different forms, including a short comma, s-shaped, long spiral or coccoid form. The diagnosis is also confirmed by cultivating the bacteria on special microaerophilic media.
- 2) Phase-contrast microscopy of bile to demonstrate organisms may provide a tentative diagnosis.
- 3) Heterophilia and thrombocytophilia are the most consistent changes in the hematology examination.
- 4) Various commercial ELISA kits have been developed for direct detection of *Campylobacter*. Most of these assays have been evaluated with human stool samples or animal feces, but their utility for detection of *campylobacter* in finch feces remains to be determined.
- 5) PCR method has been widely used for detection and identification of *Campylobacter* spp.

Prevention

The following criteria should be considered to prevent and control the *campylobacteriosis*.

- 1) **Biosecurity**

Finch aviary can be contaminated by *Campylobacter* in many different ways. Biosecurity keeps the disease from entering into the finch's facility and reduces the colonization level of *campylobacter* insusceptible finches. So each method of disease transmission and spread must be noticed in this policy. Because *Campylobacter* spp. are commonly present in the environment, it is rather difficult to eliminate *campylobacter* from finch aviaries by biosecurity practices alone. Some studies investigated competitive exclusion as a means of preventing *campylobacter* colonization of *Campylobacter* spp. in birds [92-94]. Several feed additives (fatty acids, plant derived additives, etc.) were also evaluated for their effects on *campylobacter* colonization in broiler chickens [95, 96]. These phenomena require further researches in finch rearing.

- 2) **Disinfection**

Chlamydiosis (Psittacosis)

Etiology and Organism Biology

Avian chlamydiosis is caused by the *Chlamydophila psittaci* which belong to the family Chlamydiaceae, order Chlamydiales. The organism is an obligate intracellular and Gram-negative bacterium. The disease in birds and humans is called chlamydiosis and psittacosis, respectively.

Epidemiology

Avian chlamydiosis has a worldwide distribution. Based on literatures, geographical areas and different test assays which give large differences.

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Psittacosis is a respiratory disease in humans. The clinical signs vary, ranging from a mild flu-like to severe pneumonia with respiratory distress and death. Common signs include fever, headache, chills, myalgia and nonproductive cough. Other signs and complications include, rash, enlarged spleen, myocarditis, endocarditis, hepatitis, arthritis, keratoconjunctivitis, and encephalitis.

Chlamydophila psittaci can be transmitted to humans and care should be taken when handling infected birds or contaminated materials. *Chlamydophila psittaci* shed in the feces or respiratory secretions of infected birds. Humans become infected by direct contact with infected birds and tissues or by inhalation of the organism.

Hosts

Chlamydophila psittaci or chlamydial antibodies have been demonstrated in about 465 bird species including 30 bird orders [97, 98].

Transmission, Carriers, Vectors, Spread

- 1) Horizontal transmission from one infected bird to another susceptible bird is an important mode of transmission. Transmission of *Chlamydophila psittaci* occurs through inhalation or ingestion of contaminated material.
- 2) Vertical transmission has been demonstrated in some species including turkeys, chickens, ducks, parakeets, seagulls, and snow geese [99, 100].
- 3) The organism is excreted in feces and nasal discharges.
- 4) Intermittent fecal shedding by subclinically infected birds may occur. *Chlamydophilas* pp. has also been isolated from the droppings of clinically normal finches [101].
- 5) In poultry, shedding may occur for several months but it is not well demonstrated in finches [102].
- 6) Common reservoirs of chlamydiae include wild and feral birds. *Chlamydophila psittaci* can be carried by and shed without any apparent effect on those hosts.

Incubation Period

The incubation period for chlamydiosis in finch is not known.

Clinical Signs

The clinical signs are non-specific, and may include apathy, debilitation, diarrhea, nasal exudates and conjunctivitis. Mortality may occur. In passerines, the disease should be expected with recurrent respiratory disease, especially if birds are exposed to psittacines.

Diagnostic Procedures

The diagnosis of avian chlamydiosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Isolation requires inoculation of the living *Chlamydophila psittaci* into cell cultures, embryonating SPF chicken eggs or mice. Samples should be preferably collected from pharyngeal or choanal slit swabs in live birds. Feces or cloacal swabs are less proper because pathogen shedding is intermittent.
- 2) The diagnosis is also made at necropsy by the presence of the chlamydial organism in impression smears from the affected organs and using special staining techniques. In birds, lungs, spleen, liver, free exudates and exudate-coated air sacs can be sampled.
- 3) A number of manufacturers produce ELISA kits for detection of *Chlamydophila* spp. in humans, but none of the kits is licensed for *Chlamydophila psittaci* in finches.
- 4) The tissues can be collected for antigen detection by PCR.

Prevention

The following criteria should be considered to prevent and control the chlamydiosis.

- 1) **Biosecurity**

Finches should be kept in aviaries without contact with contaminated equipment or premises. Contact with reservoirs or vectors such as wild and feral birds should also be prevented.

- 2) **Disinfection**

Chlamydophila is highly susceptible to chemicals that affect their lipid content or their cell walls. Commercial disinfectant such as quaternary ammonium, benzalkonium chloride, silver nitrate, alcoholic iodine solution, 70% ethanol, 3% hydrogen peroxide, and lipid solvents will inactivate the bacterium.

Colibacillosis

Etiology and Organism Biology

The etiology of colibacillosis is avian pathogenic *Escherichia coli* (APEC). A particularly virulent O86 APEC, recently reclassified as *Escherichia albertii*, caused significant mortality in free-living finches in Britain [103, 104]. *Escherichia coli* is categorized in the family Enterobacteriaceae and is a gram-negative, nonspore-forming bacillus. The organism is often considered as secondary pathogen and should be considered as a sign of poor hygiene or management conditions. Infection with *Escherichia coli* is also the result of fecal contamination of water, food, perches, and environment.

Epidemiology

Escherichia coli has a worldwide distribution. Outbreaks of colibacillosis have been reported in finches [105-107].

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

The enterohemorrhagic strains of *Escherichia coli* (EHEC) (e.g., O157:H7) and some strains of extra-intestinal pathogenic *Escherichia coli* (ExPEC) are considered to be zoonotic pathogens. The EHEC cause intestinal injuries while ExPEC cause disease outside the intestinal tract. Infection with EHEC causes abdominal cramps, watery or bloody diarrhea, hemolytic uremic syndrome (HUS), thrombocytopenia, microangiopathic hemolytic anemia and renal failure. Infection with ExPEC causes various illnesses, including septicemia, urinary infection and newborn meningitis [108].

Hosts

Most avian species are susceptible to colibacillosis.

Transmission, Carriers, Vectors, Spread

- 1) In diseased passerine birds, *Escherichia coli* are often shed from the feces, but in healthy passerines, the bacterium is absent in the intestines.
- 2) Direct or indirect contact with infected bird or feces can introduce *Escherichia coli* into the finch's aviary. Free-living birds such as waterfowl [109-111] and passerine birds [112, 113] are an important source of infection because they are colonized with strains that are already adapted to avian species.
- 3) In nesting birds, infection can occur at any time from egg formation, incubation period or hatching time following fecal contamination.
- 4) Houseflies (*Muscadomestica*) serve as mechanical vectors of *Escherichia coli*.

Incubation Period

The time between infection and onset of clinical signs varies with the type of disease produced by *Escherichia coli*. The incubation period depends on the factors such as dosage of bacterium, the age of exposure, etc.

Clinical Signs

Clinical signs depend on the specific type of disease produced by *Escherichia coli*. Localized infections result in milder clinical signs than systemic infection. The clinical signs are not pathognomonic. In general, clinical signs include chronic weight loss, diarrhea or severe septicemia (lethargy, anorexia, weakness, fluffed appearance, and death). *Escherichia coli* can also cause polyuria, infertility, egg-related peritonitis, conjunctivitis, rhinitis, respiratory infections, ingluvitis, arthritis and death. Infection during the first few days of life can cause enteritis from enterotoxin production. The chicks can quickly dehydrate and become cachexic. The nests become dirty, wet and yellowish. The brooding female also appears wet. Young birds may die within a few days. In one case of enteric colibacillosis, the passage of whole seeds in the droppings was noted before death [105]. Localized infections in various tissues may also occur. Clinical signs of co-infections or predisposing factors are often seen concurrently with signs of *Escherichia coli* infections.

Escherichia coli is also cultured from passerine nestlings with diarrhea ('sweating disease'). Septicemic form of colibacillosis is a major cause of mortality in newly arrived shipments of finches.

Diagnostic Procedures

The diagnosis of colibacillosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Diagnosis is confirmed by demonstrating the *Escherichia coli* from lesions typical of colibacillosis.
- 2) Detection of acute phase proteins or calculating the heterophil/lymphocyte ratio can serve as nonspecific markers of the inflammatory condition such as colibacillosis.

Prevention

The following criteria should be considered to prevent and control the colibacillosis.

1) **Biosecurity**

Prevention of colibacillosis is associated with the identification and elimination of sources of infection such as avoiding contaminated feed, water, dust, animal feces, rodent droppings and wild birds. Protecting the finches from viral infections increases host resistance. Pelleted feed has fewer *Escherichia coli* than mash and reduces the colibacillosis. Proper ventilation reduces the levels of bacteria in enclosed aviaries. Wet perch provides a proper environment for *Escherichia coli* to persist and reach high numbers.

2) **Disinfection**

Physical conditions such as dryness and heat are detrimental to the organism. Inactivation of most strains occurs at temperatures ranging from 60 °C for 30 minutes to 70 °C for 2 minutes. *Escherichia coli* is destroyed by disinfectants such as chlorine dioxide.

Erysipelas

Etiology and Organism Biology

The etiologic agent of erysipelas is *Erysipelothrix rhusiopathiae*. The organism belongs to the family Lactobacillaceae and is a small Gram-positive bacterium.

Epidemiology

Erysipelothrix rhusiopathiae is occasionally isolated from passerine [114].

Economic Significance

Erysipelas can cause death in avian and is considered to be a zoonotic pathogen. Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Infection with *Erysipelothrix rhusiopathiae* in humans is called erysipeloid that may be a local or systemic, and occasionally fatal infection. The clinical manifestations of infection with *Erysipelothrix rhusiopathiae* in humans are localized cutaneous lesion, pain, swelling, arthritis and peritonitis. Diffuse cutaneous and systemic forms of the infection are much less common. Transmission occurs by the bacterium entering into a cut or abrasion wound when working with infected birds or contaminated environments. Person-to-person transmission of *Erysipelothrix rhusiopathiae* has not been improved.

Hosts

Erysipelas affects a wide variety of avian, mammalian reptiles and amphibians.

Transmission, Carriers, Vectors, Spread

- 1) Contaminated material is an important source of infection.
- 2) Entry through breaks in the mucous membranes or skin is the most frequent portal of entry.
- 3) Fishmeal and fish are probable sources of infection for avian species.
- 4) Soil serves as a temporary reservoir for the organism.
- 5) Mosquito and fly are considerable in mechanical transmission of *Erysipelothrix rhusiopathiae*.
- 6) Rodents, pigs and red mite have all been implicated as reservoirs for the bacterium.

Incubation Period

The incubation period of erysipelasis not defined in finch.

Clinical Signs

Erysipelas is a septicemic disease, which generally occurs sporadically in various avians. Clinical signs of the disease are suggestive of acute to subacute septicemia [115, 116].

Diagnostic Procedures

The diagnosis of erysipelas is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) *Erysipelothrix rhusiopathiae* can be isolated by microbiological culture from infected organs. Rapid presumptive diagnosis is provided by demonstrating the bacteria in smears from the liver, spleen, heart blood, or bone marrow. The bacterial morphology is clumps and segregated Gram-positive, beaded, slender, and pleomorphic rods.
- 2) Immunoperoxidase staining can be used to detect *Erysipelothrix rhusiopathiae* from the affected tissues [117].
- 3) PCR method has been used for detection and identification of *Erysipelothrix rhusiopathiae* [118-120].

Prevention

The following criteria should be considered to prevent and control the erysipelas.

1) Biosecurity

Finch aviary can be contaminated by *Erysipelothrix rhusiopathiae* in many different ways. Biosecurity keeps the disease from entering into the finch facility and reduces the bacterial load in aviaries. So each method of disease transmission and spread must be noticed in this policy. It has been suggested that various environmental factors (e.g., rainy and cold weather, sexual maturity) make avian species more susceptible to *Erysipelothrix rhusiopathiae* infection. This may apply to aviary of finches [121].

2) Disinfection

Disinfectants such as phenol, quaternary ammonium, chlorine and sodium hydroxide are effective against *Erysipelothrix rhusiopathiae*. These disinfectants are only effective when surfaces are clean and devoid of any material.

Listeriosis

Etiology and Organism Biology

Listeriosis is caused by *Listeria monocytogenes*. Thirteen serotypes of pathogen have been recognized.

Epidemiology

Listeria monocytogenes has a worldwide distribution. The organism is commonly found in feces and soil. Wet conditions are risk factors for disease.

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

The *Listeria monocytogenes* is important because of its ability to cause human disease following contact with infected birds. Serotypes 1/2a, 1/2b, and 4b are often associated with human disease. Clinical manifestations of human infections with *Listeria monocytogenes* vary, including gastroenteritis, septicemia, focal infections such as brain and hepatic abscesses, conjunctivitis, endocarditis, cholecystitis, joint abscesses, osteomyelitis and skin infections. Infection of pregnant women may cause meningoencephalitis in neonates and fetal death. In immunocompromised adults, septicemia and meningoencephalitis may also occur [122-124].

Hosts

Outbreaks of listeriosis caused by *Listeria monocytogenes* occur in chickens, turkeys, waterfowl, pigeons, passerines and other avian species [125].

Transmission, Carriers, Vectors, Spread

Infection can occur following inhalation, ingestion, or wound contamination.

Incubation period

It is not defined in finches.

Clinical Signs

Young birds are most susceptible. Septicemic and encephalitic forms of listeriosis are noticed in birds [126]. Birds may exhibit emaciation, diarrhea, depression and neurological signs (incoordination, ataxia, torticollis, and opisthotonos).

Diagnostic Procedures

The diagnosis of listeriosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

Listeria can be isolated by microbiological culture from infected organs. For identification of species, *Listeria* isolates should be evaluated in haemolysis, D-mannitol, D-xylose and L-rhamnose.

Prevention

The following criteria should be considered to prevent and control the listeriosis.

1) **Biosecurity**

Prevention of listeriosis is associated with identification and elimination sources of infection such as avoiding wet conditions, contaminated water and soil, and animal feces.

2) **Disinfection**

Tuberculosis

Etiology and Organism Biology

Mycobacterium avium complex and *Mycobacterium genavense* are the most common mycobacterial species, which are associated with passerines disease.

Epidemiology

Avian tuberculosis is worldwide in distribution. Tuberculosis with *Mycobacterium avium* complex is most commonly found in finches [127-129]. Avian mycobacteriosis appears to be overrepresented in Gouldian Finches compared with other passerines [129]. *Mycobacterium genavense* is also involved in avian tuberculosis, and is isolated from human patients with AIDS.

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

The *Mycobacterium avium* complex and *Mycobacterium genavense* are responsible for most cases of human tuberculosis [130]. The common clinical signs associated with human infection are weight loss, fever, night sweats, chills, pulmonary disorder (chronic cough, dyspnea), lymphadenitis (swelling of the submandibular, submaxillary, cervical, or preauricular lymph nodes), and disseminated infection. Human may be infected by ingestion or inhalation of organisms from the environment.

Hosts

All species of passerines can be infected with *Mycobacterium avium* complex and *Mycobacterium genavense*.

Transmission, Carriers, Vectors, Spread

- 1) Mycobacteria are ubiquitous in the environment and are commonly isolated from soil, litter and water. Therefore, the contaminated environment is the most important source for the transmission of the organism to passerines.
- 2) Infection can occur by ingestion (via infected feces, contaminated food and water) or inhalation of organisms.
- 3) Birds may serve as a reservoir of some *Mycobacterium avium* strains.
- 4) Insects may act as mechanical vectors.
- 5) Infected birds shed mycobacteria in their feces and fecal material is important for the dissemination of avian tuberculosis.
- 6) The respiratory tract is a potential source of organism, especially if lesions occur in tracheal and lung.
- 7) Mycobacteria can be disseminated by the carcasses of the infected birds.
- 8) The spread of mycobacteria by contaminated shoes, equipment, and materials (crates and feed sacks) can occur from diseased to healthy aviaries.
- 9) Wild and imported birds may be infected with mycobacteria and spread the organism to finch's aviaries.

Incubation Period

The incubation period following infection can be months or years.

Clinical Signs

Tuberculosis is commonly an enteric infection, respiratory or disseminated. Tuberculosis in passerines usually produces diffuse granulomatous, noncaseous lesions rather than discrete tubercles as found in galliforms [87, 129]. Clinical signs are not pathognomonic. In advanced infections, the most consistent clinical signs of avian tuberculosis are weight loss and severe muscle atrophy. Feathers may have a dull and ruffled appearance. Gross abnormality such as abdominal distension, fluid-filled, hepatomegaly and thickened intestines may be palpable. Lameness may be present in patients with arthritis or osteomyelitis. Sudden death may be the

only presenting sign, although affected birds are usually thin [127-129, 131]. The CNS alteration has been reported in finches [132]. Affected birds may die within a few months or live, depending on severity of the disease. A bird may die suddenly due to hemorrhage from the rupture of the internal organs such as liver or spleen.

Diagnostic Procedures

The diagnosis of tuberculosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Diagnosis is confirmed by demonstrating the acid-fast bacteria in tissue smears, especially in the intestinal wall, liver, spleen and bone. Fecal acid-fast stains may reveal the organism antemortem, but the organism usually sheds intermittently.
- 2) Diagnosis is possible using PCR techniques on cloacal swabs or infected tissues.
- 3) Diagnosis can be based on marked leukocytosis with monocytosis and elevations in AST and bile acids.
- 4) Radiographs may show tissue enlargement (enlarged liver, kidney and spleen), as well as bone abnormality (focal, cloudy densities in the medullary cavities of long bones with osteolysis).
- 5) Endoscopy and biopsy can confirm the diagnosis. Endoscopy reveals granulomas in the internal organs such as liver, spleen and intestinal tract. There may be hepatomegaly, splenomegaly and thickened intestines.

Prevention

The following criteria should be considered to prevent and control the tuberculosis.

1) **Biosecurity**

Prevention of tuberculosis is associated with the identification and elimination of sources of infection such as avoiding contaminated water and soil, and animal feces. Providing proper fencing can prevent exposure from wild birds and prevent housing previously used by infected birds. Removal of birds from soil-floored aviaries is an important way of minimizing the impact of this disease within a collection. Collecting the eggs from the affected flock and fostering them under less susceptible finches has also been suggested. Carcasses of infected birds that show lesions of tuberculosis must be burned. In some instances, the infected birds may be culled due to the possible zoonotic implications. When morbidity is high in an aviary, it is practical to eliminate the infected birds and establish a new flock in the new environment.

2) **Disinfection**

Mycobacteria may resistant to typical chemical disinfection. They can survive for several months to a few years in the environment. Ordinarily, it is impractical to keep the environment satisfactorily safe by disinfection.

Salmonellosis

Etiology and Organism Biology

Paratyphoid salmonellae are members of the family Enterobacteriaceae, which are (usually) motile, gram-negative, nonspore-forming rods and often nonhost-adapted bacteria. They affect birds, animals and humans.

Epidemiology

Paratyphoid salmonellae found nearly ubiquitously in wild and domestic birds. Outbreaks of the disease have been reported in finches [133-135].

Economic Significance

Salmonellosis causes economically significant losses for owners in many regions, especially in areas where finch rearing is a source of income. The disease also absorbs large investments of public resources in testing, prevention and control efforts.

Public Health Significance

Salmonella Typhimurium and *Salmonella Enteritidis* are the 2 most common paratyphoid salmonellae isolated from humans. Infection with paratyphoid salmonella may cause fever, gastroenteritis, acute enterocolitis, headache, abdominal pain, diarrhea, nausea and vomiting. Often the disease is self-limiting after 3-7 days. Adverse consequences of bacteremia may occur and include disseminated focal infections and arthritis. Transmission can be made by direct contact with infected feces or indirectly by the consumption of contaminated food products. Infection occurs by the fecal-oral route.

Hosts

Paratyphoid salmonellae infect a wide variety of hosts, including invertebrate and vertebrate (wildlife, domestic animals, birds and humans) [136-139].

Transmission, Carriers, Vectors, Spread

- 1) Paratyphoid salmonellae can be introduced into finch's aviary from various sources. For example, contaminated feeds, vegetable, cereals, vermin or wildlife are potential sources of salmonella. Feeds containing contaminated animal proteins may also contain salmonella.
- 2) Paratyphoid salmonellae are able to colonize into the gastrointestinal tracts of a wide range of hosts including animal and birds. Feces of infected birds are one of the most common sources of infection.
- 3) Ingestion of contaminated food or water is the most common mode of transmission.
- 4) In poultry, vertical transmission of salmonellae to the progeny of infected breeding flocks can result in internal or external contamination of eggs. Transovarian transmission of infection to progeny was also reported [140]. These forms of transmission need future evaluation in finches.
- 5) Chronically and asymptomatic infected birds may present.
- 6) Insects and other invertebrates, including flies [141], ground beetles [142], cockroaches [143], red mites [144], and centipedes [142] can carry salmonella

organisms externally or internally. Mice [145] and roof rats [146] are important vectors for salmonella.

- 7) Contaminated dust from feces and feathers may aid aerosol spread [101].
- 8) Improper handling and sanitation can spread the organism through the contaminated seed, fruits, vegetables, drinking water and food.

Incubation Period

In general, the incubation period of the disease in birds can be as short as 3-5 days in acute cases.

Clinical Signs

Salmonellosis can be peracute, acute, chronic or subclinical depending on the number of organisms, the age and condition of the host. In passerines, the disease more often has a chronic course.

The clinical signs are often non-specific and include depression, lethargy, anorexia, weight loss ruffling of the feathers, diarrhea, soiled vent and dehydration. High mortality, neurological signs (convulsions), crop stasis lameness and wing droop may also present. Lameness and wing droop are associated with septic arthritis. In breeding birds, there is often poor hatching or excessive fledgling mortality.

Diagnostic Procedures

The diagnosis of salmonellosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) The diagnosis is confirmed by isolation and identification of causative organisms.
- 2) Various commercial ELISA kits have been developed for direct detection of salmonella. Agglutination tests have also been used to detect infections with paratyphoid salmonellae. However, their utility for detection of salmonella in finches remains to be determined.
- 3) PCR method has been widely used for detection and identification of *Salmonella* spp.

Prevention

The following criteria should be considered to prevent and control the salmonellosis.

1) **Biosecurity**

Finch's aviary can be contaminated by salmonella in many different ways. So each method of disease transmission and spread must be noticed in this policy. Control of vectors and prevention of contamination of food and water are required. Furthermore, good hygiene practices must be implemented. Some studies investigated competitive exclusion as a means of preventing salmonella colonization [147, 148]. This phenomenon requires further researches in finch rearing.

2) **Disinfection**

Salmonellae can survive for long periods in organic matter, feces and dirt (up to two years). Salmonellae are generally susceptible to destruction by heat and irradiation

(gamma and ultraviolet radiation) [149-151]. Steam pelleting treatment of feed under standard conditions inactivates salmonellae.

Chemical disinfectants such as phenolic and quaternary ammonium compounds, formalin and formaldehyde fumigation can be used in finch's house and facilities. Organic acids such as zinc acetate and zinc propionate can be applied in feed. Disinfectants such as formaldehyde [152], hydrogen peroxide [153], ozone [149], lactic acid [154] and peroxidase catalyzed compounds [153] were applied to hatching eggs.

Staphylococcosis

Etiology and Organism Biology

The etiologic agent of staphylococcosis is *Staphylococcus aureus*. The organism belongs to the family Staphylococcaceae and genus *Staphylococcus*. Staphylococci are Gram-positive and coccoid. They appear in clusters when grown on solid media and in liquid media, they may be found in short chains. *Staphylococcus aureus* frequently colonizes on the skin and mucous membranes of birds, humans and animals. It is a commensal bacterium and frequently causes clinical diseases.

Epidemiology

Staphylococcus aureus has a worldwide distribution. Outbreaks of staphylococcosis have been reported in finches [19].

Economic Significance

Staphylococcal infections cause economic losses due to bird losses from septicemia. It is also a significant zoonotic disease and treatment, prevention or control measures requires the aid of formal economic appraisal [155, 156].

Public Health Significance

Staphylococcus aureus causes various clinical manifestations ranging from cutaneous infections (cellulitis, impetigo, abscesses, folliculitis, carbuncles and furuncles) to septicemia and death. Bloodstream spread of localized infections may result in adverse consequences including endocarditis, osteomyelitis, arthritis, meningitis, pneumonia, and sepsis. Infants and the chronically ill patients are at increased risk of exhibiting severe skin alterations. In recent years, antibiotic-resistant strains, especially methicillin-resistant *Staphylococcus aureus* (MRSA), have become increasingly common [157]. In human, the anterior nares are the important site for bacterium colonization. Transmission is due to direct or indirect contact. Hands are the most important vehicle for transmission. Airborne transmission may also occur.

Hosts

All avian species are susceptible to staphylococcal infections.

Transmission, Carriers, Vectors, Spread

In general, infection can occur following a breakdown in the natural defense mechanisms of the host. In most cases, this would be due to a skin wound or inflamed mucous membrane. Furthermore, hematogenous spread of pathogen is a locus of infection.

Incubation Period

The incubation period is short in poultry, but is not defined in finch.

Clinical Signs

The clinical signs include dermatitis, folliculitis, abscesses, conjunctivitis, sinusitis, bumble foot, arthritis, pneumonia and death. In generalized skin infection, the skin is usually very pruritic, and often erythematous. *Staphylococcus aureus* has been associated with pododermatitis, respiratory disease, gastrointestinal alterations and septicemia in finches [105].

Diagnostic Procedures

The diagnosis of staphylococcosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Staphylococcosis is diagnosed by microbiological culture from suspected exudates or swabs of infected organs.
- 2) Cocci will be seen in the impression smears.
- 3) In skin infection, diagnosis requires a skin biopsy (including follicles) and culture.

Prevention

The following criteria should be considered to prevent and control the staphylococcosis.

- 1) **Biosecurity**
- 2) **Disinfection**

Staphylococci are usually hardy and remain viable for long periods in exudates.

Yersiniosis

Etiology and Organism Biology

Yersiniosis is an infectious disease caused by *Yersinia pseudotuberculosis*. The organism is one member of a generic triad of pathogenic bacteria within the family Enterobacteriaceae. *Yersinia* spp. are Gram-negative ovoid to coccoid rods that are able to replicate in the environment at low temperatures (+4°C) if provided the proper sources of organic nitrogen.

Epidemiology

The geographical distribution of the organism includes many parts of the globe. Infection with *Yersinia pseudotuberculosis* is regularly seen in wild finches [114, 158-160].

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Human infection is 1) related to consumption of food contaminated from avian or rodent sources and 2) person-to-person spread. *Yersinia pseudotuberculosis* causes abdominal disease, which includes enteritis, typhlitis, mesenteric lymphadenitis, and abscessation of liver and spleen. The disease also results in septicemia, abdominal pain, fever, simulating acute appenditis and arthritis.

Hosts

Infection has been described in various species of birds, mammals and rodents [161].

Transmission, Carriers, Vectors, Spread

- 1) Infection is probably spread by contamination of food by an infected host. The organism may enter through the intestinal mucosa or through breaks in the skin.
- 2) *Yersinia pseudotuberculosis* can be a normal gut inhabitant of a variety of migratory avian species and this may be relevant to the introduction of bacterium into an area.
- 3) Natural reservoirs include birds and rodents.
- 4) Birds, rats, mice, and other small rodents may become infected and not develop the disease. They are considered as chronic carriers of *Yersinia pseudotuberculosis* with fecal shedding of the organism. These animals are believed to serve as the primary reservoir of infection.
- 5) Free-range birds are considered asymptomatic carriers.

Incubation Period

The incubation period of yersiniosis is not defined in finch.

Clinical Signs

The clinical signs are non-specific and may be associated with peracute, acute or chronic clinical signs. Peracute death without clinical signs may occur. Clinical signs following acute disease include lethargy, ruffling of the feathers, debilitation, dehydration, diarrhea and dyspnea. Emaciation, wasting and flaccid paresis or paralysis are described with subacute or chronic cases [159, 160].

Diagnostic Procedures

The diagnosis of yersiniosis is based on clinical symptoms, histopathological examination, bacterial isolation and laboratory diagnostics.

Laboratory Diagnostics

Laboratory confirmation requires isolation of *Yersinia pseudotuberculosis*. Rod-shaped bacteria are seen in impression smears from affected organs, and diagnosis is confirmed by culturing the bacterium.

Prevention

The following criteria should be considered to prevent and control the yersiniosis.

- 1) **Biosecurity**
- 2) **Disinfection**

SECTION 3: FUNGAL DISEASES

Cryptococcosis

Etiology and Organism Biology

Cryptococcosis is a fungal infection caused by *Cryptococcus neoformans*, a member of the genus *Cryptococcus*. The fungus reproduces by budding and cells are spherical and surrounded by a thick capsule.

Epidemiology

Cryptococcus neoformans has a worldwide distribution. The disease is reported in passerines as well as finches, but it is very rarely seen as a serious problem in these birds [162, 163].

Economic Significance

Cryptococcosis is a significant zoonotic disease. Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Human infection with *Cryptococcus neoformans* occurs most frequently in immunocompromised persons. The central nervous system alteration (meningitis) and pulmonary diseases are the most frequent clinical diseases. Humans, birds and animals acquire infection from environmental sources. Humans are infected with *Cryptococcus neoformans* by inhalation of yeast cells or basidiospores from the environment. Owners must use extreme care when handling contaminated materials that may contain yeast cells or basidiospores. Most human infections occur through contact with contaminated exudates, fecal material and non-clinical infected or diseased birds. Person-to-person transmission has been reported [164].

Hosts

Birds, humans and animals are infected with *Cryptococcus neoformans*[165, 166].

Transmission, Carriers, Vectors, Spread

- 1) Birds usually acquire infection from environmental sources.
- 2) *Cryptococcus neoformans* may be carried asymptotically in the upper respiratory tract.

Incubation Period

The incubation period following natural infection is not defined in finches.

Clinical Signs

In birds, the central nervous system, respiratory tract and digestive tract may be involved. Infections may produce necrotic granulomatous lesions and characteristically thick, pale, gelatinous exudates. *Cryptococcus neoformans* has been reported to cause subcutaneous nodules on the head and body skin, nodular lesions on the face and beak, beak necrosis, nasal and sinus infections, pulmonary diseases and air sac diseases [75, 105, 167, 168].

Diagnostic Procedures

The diagnosis of cryptococcosis is based on clinical symptoms, histopathological examination, fungal isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Infections can be diagnosed by culturing the organism.
- 2) Histopathology is a useful method of diagnosis.
- 3) Mucicarmine stain is used to demonstrate the thick capsule and budding spores.
- 4) Gram's stain, India ink, and Wright's stain have also been used to diagnose this infection. Wright's-stained smears of exudates often reveal encapsulated yeast organisms measuring 6 to 10 μm within 8 to 12 μm non-staining capsules.

Prevention

The following criteria should be considered to prevent and control the cryptococcosis.

- 1) **Biosecurity**
- 2) **Hygiene**

Dermatophytosis

Etiology and Organism Biology

Dermatomycosis are occasionally reported in passerines. *Microsporium* spp. and *Trichophyton* spp. are the most common etiological agents. The infection is contagious and transmissible to humans.

Epidemiology

Dermatomycosis has a worldwide distribution, but its occurrence is usually sporadic.

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Dermatophytes affect keratinized areas of the body, including the skin, hair and nails. Alterations begin as small areas of erythema and scaling, and subsequently spread peripherally. Transmission occurs by direct contact with infected birds or humans, or indirect contact via contaminated fomites. Dermatophyte infections can transmit from person-to-person while lesions are present.

Hosts

Dermatomycosis occurs in birds, humans and animals.

Transmission, Carriers, Vectors, Spread

- 1) The infection is contagious. Therefore, transmission may occur by direct contact with infected birds or indirect contact via contaminated fomites.
- 2) The organism may remain viable on contaminated objects for a long period.
- 3) Contaminated soil maybe considered as a reservoir.

Incubation Period

The incubation period following natural infection is not defined in finches.

Clinical Signs

In passerines, dermatomycosis generally causes alopecia of the head and neck, or hyperkeratosis.

Diagnostic Procedures

The diagnosis of dermatomycosis is based on clinical symptoms, histopathological examination, fungal isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Infected tissues should be stained with periodic acid-Schiff or Gomori's methenamine silver stains to evaluate the fungal morphology.
- 2) For visualizing the hyphae, skin scrapings can be treated with 10% KOH on a glass slide, which is then gently heated over a flame. Scrapings can also be cultured on sabro dextrose agar for microbiological examination.

Prevention

The following criteria should be considered to prevent and control the dermatomycosis.

- 1) **Biosecurity**

Prevention of dermatomycosis requires management protocols that remove the source of infection by preventing contact with infected birds and animals as well as contaminated fomites.

- 2) **Hygiene**

Use of examination gloves is encouraged to prevent transmission to owners.

Histoplasmosis

Etiology and Organism Biology

Histoplasmosis is caused by the fungus *Histoplasma capsulatum*, which is a mycotic infectious, but not a contagious disease, which has been reported in human and zoo birds. The soil-borne organism has the potential to grow within dirt substrates of enclosed aviaries and is commonly associated with fecal material from birds. The *Histoplasma capsulatum* is a dimorphic fungus that appears as an environmental mold and as yeast in its warm-blooded hosts.

Epidemiology

Histoplasma capsulatum has worldwide distribution and is endemic in some areas including eastern and central USA. The disease is reported in passerines, but it is very rarely seen as a serious problem in these birds [169].

Economic Significance

Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

In human, histoplasmosis produces various diseases, including sporadic infections or acute pulmonary histoplasmosis that is characterized by fever, dyspnea, nonproductive cough, myalgia and chest pain. Most human infections are usually self-limiting, but immunocompromised cases or those exposed to a large volume of organisms, may exhibit severe respiratory distress. *Histoplasma* grows in the soil, particularly in areas contaminated with bird droppings such as aviaries and wild bird roosts [55]. Humans become infected by inhalation of airborne microconidia. Vertical transmission has occurred, but contact transmission from animal-to-person or from person-to-person is not reported [170, 171].

Hosts

Histoplasmosis occurs in birds, humans and animals.

Transmission, Carriers, Vectors, Spread

- 1) Infection is acquired by inhalation of conidia produced by the mold form.
- 2) *Histoplasma capsulatum* grows in soil and material contaminated with bird droppings.
- 3) *Histoplasma capsulatum* is found in the bird house, litter, and bird roosts.
- 4) Bird droppings are a nutrient source for the growth of the organism in the soil.
- 5) The organism can be carried on the wings, feet, and beaks of birds and contaminate soil under roosting sites or manure accumulations inside or outside buildings.

Incubation Period

The incubation period is not defined in finches.

Clinical Signs

In birds, the most common histoplasma infection is considered as respiratory disease. An initial pneumonia can progress to disseminated disease with the formation of necrotic granulomas.

Diagnostic Procedures

The diagnosis of histoplasmosis is based on clinical symptoms, histopathological examination, fungal isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) In histopathological examination, the characteristic of the disease is histiocytic to granulomatous inflammation with intra-cytoplasmic budding yeasts measuring 2-4 μm in diameter.
- 2) Histoplasmin sensitivity test has also been used to diagnose this infection

Prevention

The following criteria should be considered to prevent and control the histoplasmosis.

- 1) **Biosecurity**
- 2) **Disinfection**

Equipment can be disinfected with phenol-based disinfectants.

Microsporidiosis

Etiology and Organism Biology

Microsporidia are intracellular obligate eukaryotic parasites related to fungi. More than 1200 species of microsporidia in approximately 150 genera have been described [172]. Among these species, *Encephalitozoon hellem* was reported in finches [173]. *Encephalitozoon hellem* is a single-celled, intracellular parasite of the phylum Microspora.

Epidemiology

Disease associated with microsporidial parasites has been described in birds since the 1980s [174]. Infection appears to be able to occur in a wide range of species of birds. Outbreak of *Encephalitozoon hellem* has been reported in finches [173].

Economic Significance

Microsporidiosis is a significant zoonotic disease. Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

In 1991, *Encephalitozoon hellem* was first recognized in patients with HIV-AIDS [175, 176]. These patients exhibited keratoconjunctivitis and sinusitis [177, 178]. Some cases of systemic *Encephalitozoon hellem* have also been reported. These patients presented with ocular disease, bronchi, severe infection of the trachea, lungs, kidneys, and the bladder [179-

181]. Recently, microsporidiosis is usually recognized as an opportunistic disease in immunodeficient patients (e.g., acquired immunodeficiency syndrome (AIDS) patients), children, elderly, transplant recipients, travelers and contact lens wearers. The four most common human microsporidian species, *Enterocytozoon bieneusi*, *Encephalitozoon intestinalis*, *Encephalitozoon hellem* and *Encephalitozoon cuniculi* have also been reported in various species of birds [182-185].

Hosts

Microsporidia infect a wide range of vertebrate and invertebrate hosts [186]. Increasing evidence strongly suggests that birds are the definitive host for *Encephalitozoon hellem* [187]. The disease is reported in various species of birds including lovebirds [188, 189], ostrich [190, 191], hummingbirds [192], cockatoo [185], parrot [193], budgerigars [194], pigeons [195, 196] and finches [173].

Transmission, Carriers, Vectors, Spread

- 1) Microsporidian spores shed in the droppings of birds.
- 2) Infected birds are major sources of infection for other birds.
- 3) Companion birds without obvious clinical illness shed microsporidian spores. These birds may be a source of spore contamination for infections in humans and birds [188].
- 4) Improper husbandry, malnutrition, and concurrent infections with other pathogens may predispose to the development of disease.

Incubation Period

The incubation period is not clearly defined in finches. Nevertheless, following natural infection in nestling Gouldian finches, mortality occurred at approximately 12 days of age [173].

Clinical Signs

Signs of *Encephalitozoon hellem* infection in birds are typically vague and nonspecific. Some infections are self limiting and do not result in disease and some present as an unexpected death [197]. The duration of antemortem signs is reported to be a few hours to several days. Depression, decreased appetite, and weight loss are the most commonly reported clinical signs. The majorities of birds that develop disease are either juveniles or are immunosuppressed or both.

Encephalitozoon hellem infection has been reported in nestling Gouldian finches (*Erythrura gouldiae*) that were being fostered by Bengalese finches (*Lonchura domestica*) [173]. The infection resulted in death in 95% of the nestlings. Clinical signs were revealed as cessation of begging for food and retarded growth. Birds died within 2 days of the onset of signs. Gouldian finches raised by their parents did not show disease and it was therefore suggested that the Bengalese finches might have been the source of the infections.

Diagnostic Procedures

The diagnosis of microsporidiosis is based on clinical symptoms, histopathological examination, fungus isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) Detection of organism RNA by molecular technique such as PCR [181, 186].
- 2) Detection of organism antigens by immunohistochemical method [198].

Prevention

- 1) **Biosecurity**

Because shedding is so common in some birds such as lovebirds, practitioners should advise owners not to keep infected or suspected lovebirds in aviaries.

- 2) **Hygiene**

SECTION 4: PARASITIC DISEASES

Avian Mite Dermatitis

Etiology and Organism Biology

Avian mite dermatitis is most frequently caused by *Dermanyssus gallinae* or *Ornithonyssus sylviarum*. They are classified as blood-sucking mites.

Epidemiology

Avian mites have a worldwide distribution.

Economic Significance

In severe infestations, mite can produce anemia and result in increased mortality, especially in fledglings.

Public Health Significance

Mites are not typically observed on human skin. They can bite people when they are cleaning cages. Furthermore, when no birds are available, the mites will seek out other food sources, including humans. Therefore, humans are an accidental host of avian mites. Common clinical signs in humans include dermatitis, pruritic erythematous papules and vesicles on the skin. Signs are often alleviated when the mites are removed.

Hosts

Broad varieties of avian species serve as the natural hosts for *Dermanyssus* and *Ornithonyssus*.

Transmission

Dermanyssus gallinae spends the day in the cracks and bird-room crevices, moving onto birds at night to feed, but *Ornithonyssus sylviarum* spends its entire life on the host. *Dermanyssus* and *Ornithonyssus* can survive at least 5 months and 3 weeks, respectively without a host [199].

Clinical Signs

Common clinical signs in affected birds are depression and anemia. In heavy infestations, respiratory symptoms and a PCV of less than 30 per cent should be suspected. Blood-sucking mite can cause serious mortality among fledglings as well as adult birds.

Diagnostic Procedures

The diagnosis of avian mites is based on clinical symptoms, gross examination, isolation of mite and laboratory diagnostics. The *Dermanyssus gallinae* may not be detected on the birds because it spends the day in the nest or bird-room, and ventures out at night to suck the bird's blood.

Intervention Strategies

Intervention strategies consists of dusting or spraying the affected birds with a safe insecticide and vacating the cage or nest during the day and thoroughly cleaning it.

Toxoplasmosis

Etiology and Organism Biology

Toxoplasmosis is caused by infection with the obligate intracellular protozoan *Toxoplasma gondii*.

Epidemiology

Toxoplasmosis is worldwide in distribution.

Economic Significance

Toxoplasmosis is a significant zoonotic disease. Treatment, prevention or control measures requires the aid of a formal economic appraisal.

Public Health Significance

Congenital infections with *Toxoplasma gondii* can result in neural disorder (hydrocephalus, intracranial calcifications, and mental retardation) and chorioretinitis. Infection of pregnant women may lead to infection of the fetus or abortion, but it is often asymptomatic. Postnatal infection is usually asymptomatic in immunocompetent children and adults, but the clinical signs, including transient cervical or occipital lymphadenopathy may also present. Immunocompromised persons exhibit severe signs including pneumonia, encephalitis, and chorioretinitis[200, 201].

Humans become infected by ingesting oocysts that are shed by cats or by consuming infected intermediate hosts. *Toxoplasma* can be transmitted from mother to fetus. Person-to-person transmission does not occur by direct contact, but transmission by blood transfusion or organ transplantation has been reported.

Hosts

Toxoplasmosis is a parasitic disease of mammals, birds, and reptiles. More than 63 species of birds and 27 species of other animals become infected from ingestion of oocysts

and develop cysts in tissues without passing oocysts in the feces [202]. Cats are the definitive host for *Toxoplasma gondii*. Mammals and birds are considered as intermediate hosts. *Toxoplasma gondii* infection is noted primarily in Galliformes and passerines [203], but has been diagnosed in other avian species such as parrots, raptors and owls [75].

Transmission, Carriers, Vectors, Spread

- 1) Cats become infected following ingesting an infected intermediate host, and will shed oocysts in their feces for 1-3 weeks following infection. Oocysts become infective at 1-5 days after excretion. Oocysts can remain viable in the environment for several months.
- 2) Cats shed the infective oocysts, which are then consumed by an intermediate host such as a bird.
- 3) The route of infection is not known, but it is suggested that oocysts excreted in cat feces get into the aviary.
- 4) Flies and cockroaches can serve as transport hosts for the toxoplasma.
- 5) Earthworms ingest *Toxoplasma oocysts* and are a source of infection.

Incubation Period

The incubation period following natural infection is not defined in finches.

Clinical Signs

In general, toxoplasmosis affects mainly the central nervous system, but the reproductive system, skeletal muscles, and visceral organs may also be affected. Sometimes, the disease is inapparent or latent, with overt symptoms resulting at times of stress or immunosuppression. In birds, clinical signs include anorexia, diarrhea, blindness, conjunctivitis, head tilt, circling and ataxia. In the acute phase of toxoplasmosis, the birds may show severe respiratory signs. Birds may become blind several weeks after infection.

Diagnostic Procedures

The diagnosis of toxoplasmosis is based on clinical symptoms, histopathological examination, organism isolation and laboratory diagnostics.

Laboratory Diagnostics

- 1) The trophozoites are identified in impression smears of infected tissues.
- 2) Diagnosis is confirmed by injecting suspensions of infected tissues into mice, chicken embryos, or cell cultures.
- 3) PCR assay has been used for detection and identification of toxoplasmosis [204].
- 4) Serological tests for avian toxoplasmosis were considered impractical because most avian species do not seroconvert using the human dye test. A number of manufacturers produce ELISA kits for detection of toxoplasmosis in humans, but none of the kits is licensed for toxoplasmosis in finches.

Intervention Strategies

The following criteria should be considered to prevent and control the toxoplasmosis.

- 1) **Biosecurity**

Prevention of toxoplasmosis requires management protocols that remove the source of infective tachyzoites and oocysts by preventing contact with cats, rodents and arthropods.

- 2) **Disinfection**

Oocysts are destroyed by ammonia, drying, and a temperature of 55°C [205].

SECTION 5: ALLERGIC DISEASES

Allergic Alveolitis

Etiology

The allergens contained in feathers, epithelium, dander or fecal dusts are associated with allergic alveolitis. It is believed that there are about 300 factors which cause this disease, and it can occur at any age [206]. Various mechanisms are involved in the pathogenesis of the disease. The major mechanism of the disease is a type III allergic reaction. The antigens enter into the bronchioles and alveoli. After the release of vasoactive amines, there is a hypersensitivity reaction and increase in vascular permeability. Another suggested mechanism in the pathogenesis of this disease is type IV (cellular) reaction. Such reaction is due to the activation of T lymphocytes and macrophages, which are involved in development of alveolitis and subsequently lung lesions.

Public Health Significance

The duration of symptoms can vary from several months to several years following antigen exposure. Three forms of the disease are recognized: acute, subacute, and chronic. In the acute form, signs appear within a short time after exposure to an allergen and include cough, difficult respiration, fever, and chills. If exposure ceases at this point, the symptoms disappear and no treatment is necessary. In the subacute form, symptoms may not be found or are difficult to see, but in the chronic form, the disease may not be visible for several months. Affected humans have a chronic nonproductive cough, exercise intolerance, and weight loss. Chronic allergic alveolitis can develop in as little as 2 years, but usually takes at 10-20 years. The consequences of the disease are impaired ventilation, a reduction in total lung capacity (TLC) and permanent lung lesions such as pulmonary fibrosis [206, 207].

Prevention

The severity of the disease can be reduced by installing air purification systems as well as wearing facemasks while cleaning cages and bathing birds. Patients diagnosed with the chronic form of the disease may have no choice except to eliminate all exposure to birds.

CONCLUSION

This chapter provides an overview of public health issues of diseases that are communicable from Fringillidae to humans. All owners that work around finches should be

made aware and educated on zoonoses. Individuals with immune dysfunction, young children, pregnant women and the elderly are at increased risk for contracting various zoonotic diseases. Common biosecurity practices, including the use of masks, gloves, boots and coveralls are all important elements for prevention of zoonotic diseases. Routine injury prevention and appropriate hand hygiene are also essential. Eating and drinking should also be done away from the finch aviary.

APPENDIX 1. ZONOTIC DISEASES POTENTIALLY PRESENT IN PASSERINES AND/OR FRINGILLIDAE

Pathogen	Diseases/Etiology
Viruses	
	Arboviral Encephalitis (Eastern equine encephalitis, West Nile viral encephalitis)
	Influenza (Orthomyxovirus type A)
	Newcastle disease (Avian Paramyxovirus type 1)
Bacteria	
	Arizonosis (<i>Salmonella arizona</i>)
	Campylobacteriosis (<i>Campylobacter jejuni</i>)
	Chlamydiosis/Psittacosis (<i>Chlamydophila psittaci</i>)
	Colibacillosis (<i>Escherichia coli</i>)
	Erysipelas (<i>Erysipelothrix rhusiopathiae</i>)
	Listeriosis (<i>Listeria monocytogenes</i>)
	Tuberculosis (<i>Mycobacterium avium</i> , <i>Mycobacterium genavense</i>)
	Salmonellosis (<i>Salmonella typhimurium</i> , <i>Salmonella enteritidis</i>)
	Staphylococcosis (<i>Staphylococcus aureus</i>)
	Yersiniosis (<i>Yersinia pseudotuberculosis</i>)
Fungi	
	Cryptococcosis (<i>Cryptococcus neoformans</i>)
	Dermatophytosis (<i>Trichophyton</i> spp., <i>Microsporum</i> spp.)
	Histoplasmosis (<i>Histoplasma capsulatum</i>)
	Microsporidiosis (<i>Encephalitozoon hellem</i>)
Parasites	
	Avian Mite Dermatitis (<i>Dermanyssus gallinae</i> , <i>Ornithonyssus sylviarum</i>)
	Toxoplasmosis (<i>Toxoplasma gondii</i>)
Allergens	
	Allergic alveolitis

**THE ROLE OF *SPHINGOMONAS PAUCIMOBILIS* IN
INTERGENERIC CO-AGGREGATION AND MIXED
BIOFILM FORMATION WITH WATER BORNE
PATHOGENIC BACTERIA IN THE DISTRIBUTED
DRINKING WATER SYSTEM:
IMPLICATIONS OF PUBLIC HEALTH RISK**

ABSTRACT

Sphingomonas a resident microorganism, is often encountered in the drinking water systems (DWDS). Its capability of growth over a range of temperatures, tolerance to chlorination and antimicrobial resistance patterns have recently raised health concerns. Several physiological aspects, for instance role of co-aggregation and biofilm formation especially with water borne pathogens by *Sphingomonas* remains largely unknown and deserve attention. In this study, a *Sphingomonas paucimobilis* strain isolated from Indian drinking water system was evaluated for its ability to co-aggregate and form mixed biofilms with *Salmonella typhimurium*, *Shigella flexneri*, *Escherichia coli* O157:H7. Strong co-aggregation of *Sphingomonas* with the waterborne pathogens *Escherichia coli* O157:H7 ATCC 32150, *Shigella flexneri* 2a and *Salmonella typhimurium* ATCC 25315 was observed by qualitative and quantitative methods with individual pathogens as well with a cocktail of the above three water borne pathogens. Highest aggregation index was observed with *Shigella flexneri* 2a followed by *Salmonella typhimurium* and *Escherichia coli* O157:H7. The aggregation with *Escherichia coli* O157:H7 could not be reversed by heat, protease and sugars (lactose and galactose). The results of this study have a strong implication on risk of mixed biofilms of these water borne pathogens in DWDS which

may have re-grown or introduced (either through leakage or faulty treatment processes) and eventually develop into biofilms with pre existing *Sphingomonas*. An effective, non invasive treatment strategy preferably aimed in disrupting signalling molecules of *Sphingomonas* may be of value, for assuring safety of drinking water.

Keywords: co-aggregation, adhesin, biofilms, *sphingomonas*, protease

INTRODUCTION

The microbial ecology of water distribution systems has been an area of continued research, driven by the necessity to design innovative and effective control strategies for ensuring safe and high-quality drinking water. Existing results of microbial ecology of drinking water distribution systems indicate that pathogen resistance is greatly affected by the biodiversity of community and interspecies relationships. Biofilms have assumed considerable significance in this regard and biofilm formation and adhesion of bacteria on different surfaces and the EPS production by biofilm forming microbes have been well studied in general (Flemming et al., 2007; Furuhashi et al., 2008; Simoes et al., 2007a; Skillman et al., 1998; Tsuneda et al., 2003). *Sphingomonas* has been a recent focus for study on account of its ubiquitous presence in water, persistence under low nutrient conditions and potentially pathogenic features highlighting the concern in the presence of these bacteria in drinking water distribution system. The biological safety issues which are caused by *Sphingomonas* in the distribution systems stem from their persistence and ability to secrete exopolysaccharides as major components of biofilm (Johnsen et al., 2000). Bereschenko et al. (2010) demonstrated that Sphingomonads were responsible for initial biofilm formation. Aggregation has been established as one of the essential steps towards biofilm formation and it depends on a range of interactions such as synergistic, antagonistic, mutualistic, competitive, and commensalism interactions (Simoes et al., 2007b). Bacterial co-aggregation is essential for the development of multispecies biofilm communities' i.e., the adherence of different bacterial species to each other. Furthermore, co-aggregation is a significant phenomenon that facilitates interaction among different bacterial species in the biofilm (Foster et al., 2004; Rickard et al., 2003a). The interactions may occur between protein adhesins and polysaccharide receptors (Kline et al. 2009; Kolenbrander et al., 2006) or between proteinaceous adhesin-receptors (Daep et al., 2008). Therefore co-aggregation of *Sphingomonas* with waterborne pathogens may assume significance in view of development of multispecies biofilms of potential concern. Few studies, however have systematically analyzed aggregation, co-aggregation and biofilm formation by *Sphingomonas* sp. isolated from drinking water (Buswell et al., 1997; Simoes et al., 2007a,b; Simoes et al., 2008; Yu et al., 2010) In an earlier study, we isolated a *Sphingomonas* sp. from public drinking water system and characterized its biofilm formation (Gulati and Ghosh, 2017); simulation studies indicated that this strain was able to form biofilms on various plumbing materials used in drinking water systems. The objective of the present study was to further characterize the aggregation and co-aggregation behavior with water borne pathogens of this *Sphingomonas* strain. We envisaged that investigations of these interactions will help shed light on the role of *Sphingomonas* in formation of mixed species biofilms and enable designing of effective treatment strategies for safe drinking water.

MATERIAL AND METHODS

Bacterial Strains and Culture Conditions

Drinking water samples were collected from twenty different municipal sites and one hundred and forty isolates were screened by growing on *Sphingomonas*- specific growth medium (Yim et al., 2010) at 30°C and 120 rpm for 24 hours. One isolate with demonstrable biofilm forming ability was selected for further studies. 16S sequence of the isolate was submitted in genbank database as *Sphingomonas paucimobilis* strain MG6. The standard strain of *Sphingomonas terrae* MTCC 7766 was used in parallel for the sake of comparison. The following water borne pathogens were used in coaggregation studies: *Escherichia coli* O157:H7 ATCC 32150, *Shigella flexneri* 2a and *Salmonella typhimurium* ATCC 25315. Prior to experiments, cultures were revived, grown on BHI agar thrice, individual colonies were inoculated in BHI (Brain Heart Infusion Broth, Himedia, India) broth and processed as described above.

Mixed Biofilm Profile by *S. paucimobilis* MG6

The mixed biofilm of *S. paucimobilis* MG6 and *S. terrae* 7766 with water borne pathogens was formed by Crystal violet assay with modifications of Merritt et al. (2005). Standardized suspension of mid-log phase bacterial cultures were dispensed in each well of the polystyrene plates and incubated at 30°C. The unbound cells were removed by inverting the micro titer plate and vigorous tapping followed by rinsing the wells with phosphate buffer (pH 7.2). The adherent cells were stained with 200µl of 1% (w/v) crystal violet solution for 5 minutes. The wells were washed with deionized water extensively and the plates were allowed to dry. Following washing, 200µl of 30% (v/v) acetic acid was added to each well for 15 minutes; 100µl aliquots were then transferred to fresh micro titer plate and the absorbance measured at 585 nm. The variation from control *S. paucimobilis* MG6 was further confirmed by SEM.

Aggregation Assay

Both *S. terrae* MTCC 7766 and *S. paucimobilis* MG6 were further explored for their aggregation property. Fifty ml of the strains were harvested in their growth phases at 7000 *g for 5 minutes at 4°C. After washing it twice in Phosphate Buffered Saline (PBS), the cells were resuspended in PBS and OD₆₀₀ was adjusted to 1.0. The adjusted stock was used for aggregation analysis.

Visual Aggregation Assay

The degree of auto- and co-aggregation was determined qualitatively by the scoring method of Cisar et al. (1979). To determine auto aggregation, both the strains were

transferred to different test tubes, while in the case of co-aggregation, the cultures were mixed in pairs with each of the three pathogen, i.e., *Escherichia coli* O157:H7 ATCC 32150, *Salmonella typhimurium* ATCC 25315 and *Shigella flexneri* 2a. The pure and mixed cultures in pairs were vortexed for 30 sec and incubated at room temperature for 72 hours. The scoring range used is as follows: 0 represents no aggregation and turbid suspension; 1 represents small uniform aggregates in a turbid suspension; 2- easily visible aggregates in a turbid suspension; 3 -clearly visible aggregates which settles leaving a clear supernatant; 4 - large flocs of aggregates that settle instantaneously (Cisar et al. 1979; Simoes et al. 2008).

Spectrophotometric Assay

In order to quantitatively determine aggregation, test cultures in triplicates were prepared as described above for auto- and co-aggregation and incubated at room temperature. One hundred microlitre of the aqueous phase was transferred to microtitre plate and absorbance was recorded at 0, 2, 4, 24, 48 and 72 hours. Percentage of aggregation was measured using the following formula:

$$\text{Percentage of Aggregation} = [(A_{600} \text{ initial} - A_{600} \text{ after incubation}) / A_{600} \text{ initial}] * 100$$

Aggregation Studies by Fluorescence Microscopy

Cell aggregates were fixed in 10 ml of a 1% paraformaldehyde solution in 1X PBS for 2 hours at room temperature. The aggregates were mounted on a sterile glass slide and allowed to dry. Stained the slides with DAPI (4',6'-Diamidino-2-phenylindole) and observed under epifluorescence microscope (Zeiss Axio Scope A1 Microscope, USA).

Coaggregation Reversal: Effect of Heat, Protease and Sugars

To study the effect of heat treatment on the aggregation ability of *Sphingomonas* and the waterborne pathogens, both treated and untreated auto- and co-aggregating bacterial pairs were used for visual and spectrophotometric analysis. The bacterial cultures were incubated at 85°C for 30 minutes for describing co-aggregation reversal by heat treatment (Kolenbrander et al., 1985). The method described by Rickard et al. (2003b) and Simoes et al. (2008) was used to understand the protease sensitivity of the aggregation. The protease type XVI from *Streptomyces griseus* (Himedia, India) was added at the final concentration of 2mg ml⁻¹ and incubated at 30°C for 2 hours. After incubation, cells were harvested, washed twice and O.D. was adjusted to 1.0 at 600 nm. The untreated and treated strains were mixed in equal ratios. The experiment was carried out in triplicates (Ramalinganam et al. 2013). To study the effect of sugars on aggregation, filter-sterilized solutions of lactose and galactose were added to coaggregating partners to final concentrations of 50 mM to study the effect of sugars.

Mixtures were vortexed and tested for coaggregation using the method of Rickard et al. (2003a).

RESULTS

Mixed Biofilm Profile by *Sphingomonas*

The sequence of the isolate has been deposited in GenBank database (Accession No KX594380). Both biomass quantity and microbial activity are the parameters mostly used to estimate the amount of biofilm (Characklis et al., 1990). The Crystal violet assay has been described as a rapid method for calculating cell biomass; maximum biofilm production occurred between 24 to 48 hours as the cells are in the late stationary phase before senescence phase starts. Cells in the stationary phase start synthesizing the EPS which facilitates the attachment of cells to the surface (Dunne 2002). Mixed biofilms (*S. paucimobilis* MG6/*S. terrae* 7766 + *E. coli*, *S. flexneri* 2a and *S. typhimurium*) exhibited variation than that observed in the controls and reached maturation with 65-70 hours by the kinetics (Figure 1). Scanning electron microscopy (SEM) was used to visualize the cell-surface of biofilm forming *Sphingomonas* with adhered pathogens on PVC coupons. Tight adherence of the biofilm cells with PVC was observed for *S. paucimobilis* with the cells being enmeshed in exopolysaccharides (Figure 2). Though *S. terrae* produced less exopolysaccharides, adherence was observed on PVC. The results suggested stable attachment of pathogen-*S. paucimobilis* biofilm on PVC matrix.

Visual Aggregation Assay

Based on the scoring method, results of auto- and co-aggregation were analyzed. No aggregation of pure cultures as well as combinations after zero hour of incubation was observed. Hence the cultures were further incubated at room temperature. Aggregation was visible as turbid suspension after 24 hours and clear supernatant with clear aggregates after 72 hours (Figure 3). Based on the visual observation, scores were provided following the scoring range used in literature (Cisar et al., 1979; Simoes et al., 2008).

Spectrophotometric Analysis

The incubation time is an important requisite for determining the aggregation index of auto-aggregating bacteria as well as co-aggregating bacterial pairs as reported by Saravan et al. (2014). Therefore the aggregation index was determined for all the cases at 0, 2, 4, 24, 48 and 72 hours. Aggregation indices of *S. terrae* MTCC 7766 and *S. paucimobilis* MG6 were calculated to be 74.5% and 82.75% respectively after 72 hours of incubation (Figure 4). Aggregation index of *Sphingomonas* with *Shigella flexneri* 2a was found to be approx. 84.8% -highest when compared to other pathogens.

Figure 1. Kinetics of mixed biofilm formation of (a) *S. paucimobilis* MG6 (b) *S. terrae* 7766 with water borne pathogens (*E. coli*, *S. flexneri* 2a and *S. typhimurium*).

Figure 4. Aggregation Index at different interval of time (a) *Sphingomonas paucimobilis* MG6 and its various combinations (b) *Sphingomonas terrae* MTCC 7766 and its combinations; where, A = *Sphingomonas paucimobilis* MG6; B = *Sphingomonas terrae* MTCC 7766; C = *Salmonella typhimurium* ATCC 25315; D = *Escherichia coli* O157:H7 ATCC 32150; E = *Shigella flexneri* 2a.

Visualization of Aggregates by DAPI

Direct staining by DAPI (4',6-diamidino-2-phenylindole) is a method of choice, the DAPI molecules bind to DNA and fluoresce intensely. The enhancement in aggregation ability of *S. paucimobilis* MG6 in the presence of three pathogens could be clearly depicted by DAPI staining. Furthermore, a cocktail of all three pathogens used to co-aggregate with *Sphingomonas* indicated a similar result. In fact the aggregating pairs showed a higher level of interactions as compared to the visual aggregation test for these strains when observed by microscopy (Figure 5 and 6).

Nature of Interactions between Bacterial Strains

The heat treated and untreated pure cultures did not aggregate either after zero hour of incubation or following 2 hours of incubation. Co-aggregation between different combinations was significantly affected ($p < 0.05$) upon heat treatment with the exception of *E.coli* O157:H7, since aggregation index remained at 80% in both treated and untreated samples (Figure 7). Several *E. coli* O157:H7 surface proteins are thought to be important for adhesion and/or biofilm formation, therefore it is possible that the treatment processes failed to exert a substantial effect on binding. Co-aggregation reversal by Lactose and galactose was not observed, suggesting possibilities with other sugars.

The inhibition of aggregation of *Sphingomonas* with its aggregating partners might be due to surface protein like attachment (Figure 8s). *Sphingomonas* with its aggregating partner, *E.coli* O157:H7 showed no decrease in aggregation index. Treatment with sugars-lactose and galactose failed to revert co-aggregation (Figure 9 & 10)–. The differential behavior observed may be attributed to the enzyme type and concentration (Goldhar, 1995) important for affecting lectins during the treatment process, in addition to the nutritive media which modulates lectin production (Gilboa-Garber, 1988; Goldhar, 1995). However, further possibility of co-aggregation reversal need also be examined with other sugars.

Figure 6. Photomicrograph of DAPI stained cells of auto- and co aggregating *Sphingomonas terrae* MTCC 7766 and its various combinations.

DISCUSSION

Previous studies have demonstrated that pathogens can be incorporated into heterotrophic drinking water biofilms enhancing their persistence (Gião *et al.*, 2008, 2009). It has also been suggested that for multi-species biofilms, it is very difficult to determine the positive or negative impact of different sessile microorganisms on pathogens, particularly the associations that occur within biofilms. Bacterial cells can interact within their own type or with other bacterial cells and facilitate the formation of biofilm. Aggregation has been well described for dental plaque isolates in complex media and aquatic species in potable water (Buswell *et al.*, 1997; Kolenbrander and London, 1993; Rickard *et al.*, 2003a). Cell to cell communication is requisite for initial colonization and therefore, biofilm formation. Both, autoaggregation and co-aggregation are significant in the process of communication. Autoaggregation in the biofilm boosts the adherence of genetically identical strains; these interactions are enhanced by increased hydrophobicity (Basson *et al.*, 2008). Whereas, in co-aggregation genetically different bacteria adhere to each other via specific molecules (Rickard *et al.*, 2003b). In the present study, we isolated and identified the *Sphingomonas* strain from municipal sites. This strain was chlorine resistant and could form biofilm in several plumbing materials commonly used in water distribution pipelines (unpublished observations). Detection of *Shigella*, *Salmonella* and *E. coli* O157:H7 from water samples of the *Sphingomonas* isolate prompted further exploration of the physiology of interactions of this isolate with water borne pathogenic bacteria. The aggregation, co-aggregation and biofilm formation by both the *Sphingomonas* sp. were evaluated. To the best of our knowledge, coaggregation of *Sphingomonas* with *E.coli* O157:H7, *Shigella* and *Salmonella* have not been reported. Our preliminary studies with the *Sphingomonas* have demonstrated the capability of this strain to produce EPS in line with earlier observations (Ashtaputre and Shah, 1995) and it also determines the immediate conditions of the life of biofilm cell (Flemming *et al.*, 2007) by providing a variable gel matrix.

Figure 10. Aggregation Index observed at different time intervals after galactose treatment (a) *Sphingomonas paucimobilis* MG6 and various combinations (b) *Sphingomonas terrae* MTCC 7766 and various combinations.

Spectrophotometric analysis of aggregates indicated that with the increase in incubation time, percentage of aggregation increased. Also, co-aggregation of *Sphingomonas* with different pathogens was higher as compared to autoaggregation of *Sphingomonas*. It was observed that co-aggregation by bacteria promotes biofilm development by facilitating the attachment to the partner species, indicating the possibility of *Sphingomonas* to form biofilms with *Shigella flexneri* (Min and Rickard, 2009). This observation may be explained by the fact that aggregation depend on morphological features of bacteria such as size and density (Cisar et al., 1979) and require adequate incubation time prior to visualization. The results indicated both *S. terrae* and *S. paucimobilis* MG6 as floc formers. It was reported that visual aggregation testing is not an authentic method of measuring interactions between aggregating pairs (Buswell et al., 1997). Therefore, use of microscopic methods to investigate the potential aggregation between co-aggregating partners becomes inevitable beyond the screening test of the visual aggregation. DAPI staining was further used to investigate the role played by this bacterium in the co-aggregate formation.

Autoaggregation has been proposed to be an important mechanism whereby a bacterial strain within a biofilm expressed polymers to enhance the integration of genetically identical strains. Autoaggregating strains of freshwater bacteria were found to be numerically dominant in freshwater biofilm communities; moreover, autoaggregation together with co-aggregation has been shown to enhance the development of freshwater biofilms (Rickard et al., 2003a). Therefore, it was important to further investigate the co-aggregative abilities of *Sphingomonas* with waterborne pathogens.

Previous studies reported that the formation of co-aggregates by bacteria is the result of specific lectin-carbohydrate interactions between aggregating partners (Cisar et al., 1979; Simoes et al., 2008). Protein molecules present on cell surface of one partner behaves like adhesin and the saccharide molecule present on other one behave like receptor (Rickard et al., 2000; Rickard et al., 2003a). The sensitivity of adhesin molecules to heat and protease has been suggested as evidence for presence of lectin-carbohydrate interactions occurring between aquatic bacteria as well as pathogens (Rickard et al., 2000; Rickard et al., 2003a).

Co-aggregation by *Sphingomonas natatoria* have been shown to be important in promoting dual species biofilms (Rickard et al., 2000) and the importance of surface proteins in mediating co-aggregation and biofilm development has been emphasized. The results of our study suggest the ability of *Sphingomonas terrae* and *Sphingomonas paucimobilis* MG6 to show aggregation and co-aggregate three water borne pathogens (albeit with variation) and role of surface proteins/lectins in according the interactions; both strains could form biofilms. The ability to co-aggregate supposedly confers protection of the *Sphingomonas* cells from directed shear forces and enables them to proceed to a multigeneric biofilm. Overall our results imply that mixed biofilms involving either or more of the pathogens with *Sphingomonas* could be of public health concern in drinking water distribution system and more effective treatment systems need to be developed in light of these observations.

CONCLUSION

The present study demonstrated that *Sphingomonas terrae* MTCC 7766 and *Sphingomonas paucimobilis* MG6 isolated from Indian drinking water distribution system

possessed abilities to form biofilm, aggregation. Co-aggregation was observed with the water borne pathogens: *Shigella flelneri*, *Salmonella typhimurium* and *E. Coli* O157:H7; coaggregation reversal studies involving heat, protease treatment and sugars (lactose and galactose) indicated possibility of surface proteins or lectin to be in mediating the interaction; however conclusive evidence of interaction in case of *E. coli* O157:H7 could not be obtained. The results of this study provide valuable insights in the physiological behavior of *Sphingomonas* specifically towards waterborne pathogens which could be important when designing interventions for water safety.

BIOGRAPHICAL SKETCH

Moushumi Ghosh

Affiliation: Professor & Head, Department of Biotechnology, Thapar Institute of Engineering & Technology (TIET), Patiala-147004, India

Education: MSc (Biochemistry), PhD (Biotechnology), Banaras Hindu University, Varanasi, India

Business Address: Department of Biotechnology, TIET, Patiala-147004, India

Research and Professional Experience:

Over 16 years of research expertise in fundamental and translational aspects of microbial biopolymers and biofilms. Led, as principal investigator more than 10 research projects funded by national agencies (DST, WTI, UGC, CSIR) supervised 5 doctoral students and over 48 masters and M. Tech students. Developed novel microarray based detection methods for water borne bacterial and protozoan pathogens in collaboration with Heriot Watt University and University of Edinburgh, UK as bilateral INDO UKIERI project. Scientific

contributions have been documented as policy and science based advocacy for sustainable water resources, in over 145 articles published in peer reviewed international journals, conferences, monographs, press and public media.

Professional Appointments:

July, 2019, Coordinator, TIET/TAU CoE for Food Security, Thapar Institute of Engineering & Technology, Patiala

February 2017 –present; Head, Department of Biotechnology, Thapar Institute of Engineering & Technology, Patiala

July 2015 –till date: Professor, Department of Biotechnology

June 2010 – July 2015: Associate Professor, Dept of Biotechnology, Thapar University, Patiala

June 2006 – June 2010: Assistant professor, Department of Biotechnology & Environmental Sciences, Thapar University, Patiala

Jan 2002 – June 2006: Lecturer, Dept of Biotechnology & Env sciences, Thapar University, Patiala

Jan 2001 – December 2002: Postdoctoral Scientist,
GSF Research Centre for Environment and Health, Munich, Germany

Honors:

Science and Technology Award for Research Excellence, EET CRS 2017; 11th June Bangalore.

Advisor, Scientific Committee of American Academy of Sciences, Environmental Technology

Overseas travel grant for scientific exchange, Department of Science & Technology, Govt of India (2016)

UKIERI, Department of Science & Technology, Govt of India (2014)

Noel Derr Gold medal: Sugar Technologist Association of India (2003)

Junior and Senior Research fellowship: Ministry of Food and Civil supplies, Govt of India (1996-1999)

GATE, Ministry of Human Resource Development, Govt of India (1996)

Performance Excellence Award, TU (2006 -2015)

Nominated Member, *lifetime*: Biotech Research Society of India,

Association of Microbiologists of India (AMI),

European Federation of Biosciences (FEBS),

Organization of Women in Science, (OWSD), Trieste, Italy.

ABSTRACT

In the traditional Chinese culture, families showed several characteristics. First, male members generally held a superior position whereas females typically occupied a submissive role. Second, under the strong influence of Confucianism, filial piety was strongly upheld with a central focus on the father-son relationship. Third, because of the importance of maintaining harmony in the family, the collective interest (i.e., family interest) was placed above individual interest. In this book we try to convey the traditional and contemporary influences of parenting and family life in Hong Kong. We

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

also attempt to conduct more theoretical integration and consider ways that can help to promote the family life of adolescents in the Chinese setting.

INTRODUCTION

Family is the cornerstone of the society. With specific reference to Hong Kong, there are several sources of the influence which affect family development. Primarily, as a Chinese society, Hong Kong families are under the influence of traditional Chinese cultural beliefs, although the related impact has gradually weakened. In the traditional Chinese culture, families showed several characteristics. First, male members generally held a superior position whereas females typically occupied a submissive role. Second, under the strong influence of Confucianism, filial piety was strongly upheld with a central focus on the father-son relationship. Third, because of the importance of maintaining harmony in the family, the collective interest (i.e., family interest) was placed above individual interest.

Because of the above attributes of traditional families, there are several characteristics of traditional Chinese parenting. First, gender-specific parenting was strongly upheld in traditional Chinese societies. For example, girls were socialized to be submissive to boys as reflected in the cultural belief of “*san cong si de*” (obeying the father before marriage, obeying the husband after marriage, and obeying the son when getting old). Second, fathers were expected to teach their children because of their superior role in the family. This is reflected in the traditional Chinese saying of “*yang bu jiao, fu zhi guo*” (it is the father’s fault to only feed his son, but not teach him). Finally, children were taught to regard family interests over their own interests, such as bringing honor to the family name. These expectations can be clearly reflected in the traditional writings guiding the behaviors of children, such as “*San Zi Jing*” (*Three character classic*) and “*Di Zi Gui*” (*Standards for being a good student and child*). In short, parenting in traditional Chinese culture can be regarded as “parent-centered” [1, 2].

As Hong Kong has been under the British rule for almost 150 years, families in Hong Kong have also been influenced by the Western cultural influences which are characterized by gender equality, respecting the interests of children, and emphasis of children rights. In terms of socialization, there are several characteristics of the related parenting characteristics. Fundamentally, children are not regarded as “property” of parents. Hence, their characteristics and interests are respected. Second, as the rights of children are emphasized, boys and girls are treated equally, such as having the equal right for getting formal education. Third, instead of focusing on suppressing one’s needs (because of the need to maintain harmony), children are encouraged to express themselves and demonstrate their talents and competence. In short, parenting under the Western influence can be regarded as “child-centered” [1, 2].

With reference to contemporary Hong Kong, families are under the influence of traditional Chinese cultural beliefs and Western ideologies. Besides, there are several social factors which also shape parenting in Hong Kong. First, with the highest housing price and cost of living in the world, both parents usually have to work to provide a sound financial foundation for the family. In fact, some parents take up more than one job in order to meet the expenses of the family. Obviously, this would adversely affect parenting quality because the related stress would have negative impact on individual and marital well-being of the couple. Second, several studies show that Hong Kong people had the longest working hours. Again,

this would adversely affect parenting quality as the availability of “quality time” of the parents may be limited. Third, poverty is a growing problem in Hong Kong. Roughly speaking, one out of four children experience economic disadvantages. Existing research findings show that poverty would adversely affect parenting quality in families experiencing economic disadvantages [3, 4]. Finally, divorce and re-marriage have grown in the past two decades. As there would be adjustment in divorced and re-married families, parenting would also be affected.

In view of the above-mentioned influences, it would be both theoretically and practically important to understand parenting phenomena in Hong Kong. Unfortunately, compared to research in the Western context, parenting research in Hong Kong are comparatively fewer. Hence, we have put together several papers on Chinese parenting and parent-child relationship in this special issue. The first four chapters are based on a large-scale study supported by the Research Grants Council of the University Grants Committee in Hong Kong. In the first paper, we examined the profiles of parental expectations in a sample of Chinese parents in Hong Kong. While Chinese parents showed conventional and high expectations on most aspects of their children’s future, they showed diverse attitudes in some areas, such as involvement in politics. In the second paper, we examined Chinese parents’ expectations towards sons and daughters where we found that there were different expectations about sons and daughters in contemporary Hong Kong. In the third paper, division of labor in parenting was examined in the same sample where parental differences in division of labour were shown. In the final paper, findings revealing profiles of Chinese parents’ beliefs about parental roles and responsibilities in Chinese parents were reported. In these four papers, besides normative profiles of responses, we also found that there were demographic correlates of parental beliefs and parenting practice amongst Chinese parents in contemporary Hong Kong.

As traditional Chinese cultural beliefs are influential for parental behaviors, we attempted to analyze a classic document on how children should be taught. In the fifth paper, we analyzed “Di Zi Gui” (Standards for Being a Good Student and Child). From the analyses, we found that some of the principles of “modern” parenting based on scientific studies are in fact reflected in Di Zi Gui, although some of the values and emphases on parenting are different in traditional Chinese and contemporary parenting. In the next paper, we attempted to review parenting in Hong Kong which provide interesting leads for theory development and future research. For example, it would be helpful to understand differences in parental influences (i.e., fathers versus mothers) on adolescent development. In the final paper, we examined how family life could be promoted via structured adolescent development programs. We argued that through positive youth development programs as exemplified by the Project P.A.T.H.S. in Hong Kong [5-8], adolescents could be helped to develop competence which would eventually promote the quality of family life.

It is our sincere hope that through this book, we can appreciate more the traditional and contemporary influences of parenting and family life in Hong Kong. With these papers, we attempt to conduct more theoretical integration and consider ways that can help to promote the family life of adolescents.

Hong Kong, PR China

ABSTRACT

Parental expectations and aspirations for their children's future is an important domain that exerts profound impacts on children's development. However, research on parental expectations in Hong Kong is grossly inadequate. Using a culturally-sensitive measure of parental expectations, the present study investigated the profiles of Hong Kong Chinese parents' expectations on their children's future and the related demographic correlates. Based on the responses of 5,707 parents recruited through a non-probabilistic quota sampling involving five generational cohorts of Chinese parents in Hong Kong, the present study showed that Hong Kong Chinese parents generally possessed conventional and high expectations on most aspects of their children's future. However, the parents possessed diverse attitudes toward children's involvement in politics, being exceptional, having a good social status, and pursuit of equality. Regarding demographic correlates, it was found that parental expectations were significantly associated with parents' age, parental role, education level, employment status, and family income. Specifically, mothers or parents who were older, receiving a lower level of education, retired or living on social security assistance or earning lower family income had more conventional and higher expectations on children's future. The present pioneer findings portray a holistic picture showing both commonality and variance of Hong Kong Chinese parents' expectations.

INTRODUCTION

According to the ecological perspective, family as the primary ecosystem where children grow up plays an important role in shaping child developmental outcomes. Parents' expectations, which represent parents' values and aspirations for their children's future achievements in education, social and economic domains, are considered one of the most influential family factors [1]. For example, parental expectations on their children's academic success were positively associated with children's learning motivation and academic performance [2-4]. There is also a wealth of empirical evidence showing that parental expectations on children's future significantly predicted children's psychosocial competence and behavior, including self-efficacy, cognitive competence, depressive symptoms, prosocial behaviors, aggression, and so forth [4-8]. To some extent, parents' actions in socialization practices stem from their parental goals and expectations about what qualities a child should have and what a child should do [6, 9].

Based on the existing literature on parental expectations on children's future, three observations could be highlighted. First of all, parents generally have a high expectation on children's academic performance and educational achievement, which is closely associated with children's developmental outcomes in academic domain [4, 10]. In fact, the majority of studies in this area emphasized only on the educational dimension where researchers operationalized parental expectations by asking parents their expectations on children's course grades or future academic achievement indicated by the highest level of education [4, 11]. In contrast, parental expectations on their children's non-academic attributes, such as independence or autonomy, self-confidence and "family-related" qualities have only been considered in relatively fewer studies. For example, it was mentioned that parents adopting progressive child-rearing beliefs often emphasize children's independence or autonomy [6]. Few recent studies stressed on the importance of "fulfilling family obligations" such as "obedience" or "respect for parents" in parental expectations [12, 13]. To conclude, in addition to the dimension of education, it is necessary to investigate parental expectations from other aspects such as career development, economic status, family obligations, positive qualities, and so forth.

The second observation is that parental expectations on children's future vary from culture to culture. According to ecocultural theory, parenting practices and behavior are guided by parental expectations and parenting goals, which are deeply rooted in cultural beliefs such as ideological values, social norms and institutional patterns [9]. While Western parents' expectations are built on individualistic values, Chinese parents are influenced by collectivistic Confucian thoughts. For example, while American mothers placed more emphases on children's independence and anticipated self-confidence and assertiveness in their children, Chinese mothers highly valued interdependence and they stressed on the importance of children's good relationships with others [14]. A recent study also suggested that Chinese parents tended to rate children's family obligations as more important than European American parents [12]. Therefore, investigation of parental expectations on children's future should be done with reference to social values and beliefs embedded in a specific culture.

A related issue is that there is a severe lack of research on parental expectations in the Chinese context. As pointed out by McCoy, Maître, Watson and Banks [15], "much of the

research around parental educational expectations has come from the United States” (p. 537). Computer searches in Feb 2019 based on Scopus for the period of 1990-2019 using the term of “parent* expectation” as the search term yielded 1,291 publications, among which 42 results are related to “child’s future”. The number dropped to 11 when using the search terms “parent* expectation”, “child* future,” and “Chinese.” One possible reason is that cultural-specific measurement tools for Chinese parents’ expectations on children’s future are basically non-existent [16]. Against this background, it is necessary to investigate Chinese parents’ expectations of their children’s future by operationally defining the concept with culture sensitivity. It is especially critical when studying the relevant topic among Hong Kong Chinese parents given Hong Kong’s unique history.

On the one hand, Hong Kong is predominantly a Chinese community where parental belief systems are profoundly shaped by Confucian philosophy. Specifically, cultivation of virtues such as “*li*” (“propriety”), “*yi*” (“righteousness”), “*ren*” (“benevolences”), “*zhi*” (“wisdom”) and “*xin*” (“trustworthiness”) is of principal importance in Confucianism. Besides, Confucian thoughts consider education the primary means of achieving personal success and highlight related attributes that lead to educational achievement, such as diligence and effort. These ideas are clearly reflected in traditional Chinese sayings like “*wan ban jie xia pin, wei you du shu gao*” (“all jobs are low in status, except study which is the highest”) and “*qin neng bu zhuo*” (“diligence is a means by which one makes up for one’s dullness”). Fulfilling family obligation constitutes another important element of traditional Chinese culture. Children are socialized to prioritize familial and societal needs rather than individual needs. For instance, “*xiao*” (“filial piety”), “*chuan zong jie dai*” (“pass the line”) and “*guang zong yao zu*” (“bring honor to one’s families”) are traditionally emphasized as children’s obligations and responsibilities. Influenced by these ideas, Chinese parents would expect their children to have high educational achievement, fulfill family obligations and develop traditional virtues such as politeness, morality, and righteousness [16].

On the other hand, after being a British colony for nearly 150 years, Hong Kong becomes a melting point for Chinese and Western cultural values. It is argued that subculture in Hong Kong is more modernized and Westernized than that of Mainland China, which may result in less collectivism and more individualism in Hong Kong than in Mainland China. Thus, although traditional Chinese values have significant influence in Hong Kong, Hong Kong Chinese parents may differ from their Mainland Chinese counterparts regarding parenting practices and socialization goals. This argument has been supported by several pieces of empirical evidence [17, 18]. However, most studies on parenting in Hong Kong were guided only by Confucian values but failed to acknowledge the different historical and cultural contexts of Hong Kong from the generalized Chinese culture [19]. This is the case in the research field of parental expectations. For example, several recent studies have investigated Hong Kong Chinese parents’ expectations on their children’s future by taking into account only traditional Confucian values [13, 20]. Therefore, to fully address the related research gaps, the investigation of Hong Kong Chinese parents’ expectations should consider both traditional Chinese values and Western values, such as democracy, independence and justice.

The third observation is that there may be linkages between parental expectations of children’s future and demographic factors, such as parental roles (i.e., fathers versus mothers), parents’ education level and economic status. This is because parents’ own knowledge, learning experiences and living conditions may exert influence on their understanding and interpretation of parenting and socialization goals. For example, Tocu’s

[21] study showed that parents with a higher level of education had stronger progressive childrearing beliefs and considered children's autonomy more important. This study also found that fathers had stronger traditional attitudes toward childrearing and valued children's conformity more than mothers. Additionally, middle-class fathers and mothers were more likely to value autonomy in their children than their working-class counterparts [22]. Apart from these indirect supportive findings, direct evidence comes from research on parental educational expectation for their children. For example, parental expectations on children's academic achievement were positively predicted by parents' own education level and family income [23-25]. However, none of these studies were carried out in the Chinese context. Furthermore, to expand the scope of research, not only the educational dimension, but also economic, familial and social dimensions of parental expectations should be covered.

To sum up, there are mainly two research gaps. First, compared with ample research on parents' educational expectation for children, there is a dearth of research considering other dimensions of parental expectations on their children's future. Second, given the unique history of Hong Kong, it is important to investigate Chinese parents' expectations in Hong Kong as a special Chinese community that is different from Mainland China. However, limited evidence is available for understanding the profiles and demographic correlates of Hong Kong Chinese parents' expectations on children's future. To address these two research gaps, the present study attempted to investigate Hong Kong Chinese parents' expectations on children's future using a culturally-sensitive measurement tool. Profile of responses and demographic correlates of parental expectations were the foci of the present study.

OUR STUDY

The present study was approved by the Survey and Behavioural Ethics Committee of The Chinese University of Hong Kong. A non-probabilistic quota sampling method was used to recruit Chinese parents from five generational cohorts between the 1970s and the 2010s in Hong Kong. With the aim of achieving a sample of 0.1% of each cohort based on the most updated census data [26], parents were recruited through multiple sources including elderly centers, NGOs, parent education association, universities, secondary and primary schools, kindergartens, and the Internet.

The final sample consisted of 5,707 participants, among whom 1,770 (31.0%) were fathers and 3,710 (61.5%) were mothers. The participants aged between 21 to 97, and the mean age of fathers and mothers was 54.11 ($SD = 12.20$) and 51.00 ($SD = 13.94$), respectively. Regarding the participants' educational achievement, around 14.2%, 17.1%, 31.1%, 6.7%, 24.2%, and 4.7% participants had an education level at primary school or below, junior secondary school, senior secondary school, matriculation, college or university, and postgraduate or above, respectively. Besides, 45.7% and 10.6% of participants had full-time or part-time jobs, respectively. Among the remaining, 17.7% were homemakers, 1.3% were unemployed or between jobs, 20.9% were retired, and 1.8% were living on social security schema. With regard to monthly family income, 21% had HK\$14,999 or below, 46% were between HK\$15,000 and HK\$49,999, and around 27% had HK\$50,000 or above. More details about the demographic profile of the respondents are reported elsewhere [27].

Measures

Multiple measures were used in the survey. The parental expectation of Hong Kong Chinese parents was the focus of the present study. The participants were asked to rate the importance of 24 parental expectations for their children's attributes on a 5-point scale (1 = "not at all important," 5 = "very important"). Sample items included "I expect my children to be able to distinguish between right and wrong," "I expect my children to respect the elders," "I expect my children to respect human rights" and "I expect my children to have a successful career". A higher score indicates that a more conventional parental expectation which represents a higher expectation as well.

The Hong Kong Chinese Parental Expectation Scale (HKCPE) used in the present study was developed by the research team using a three-step process. First, in-depth individual interviews with 60 parents (two 1.5-hour interviews for each parent) on their offspring rearing experiences were conducted. Based on the interviewees' responses, a culturally adapted scale on parents' expectations on their children's future was created. Second, four professors in the research team conducted expert rating to examine the face validity of the original items. After dropping redundant or ambiguous items and items which were difficult to categorize, 34 items were retained to form a preliminary quantitative measure. Third, the 34-item scale was subject to preliminary reliability analyses in a pilot validation trial involving 805 Hong Kong Chinese parents. After deleting 10 items with low reliability, a 24-item HKCPE was obtained and further tested in the present study. The 24 items represented parental goals reflecting both traditional Chinese cultural (e.g., respect for the elders, honesty, and establishment of a normal family) and Western cultural (e.g., independence, respect for human rights, and pursuit of equality) values.

Apart from the above measure, we also included measures of gender expectation differences, division of labour in parenting tasks, beliefs in parental roles and responsibilities [27]. Finally, we also collected information on the socio-demographic characteristics of the respondents, including age, parental role (i.e., fathers or mothers), educational achievement, employment status, and family income.

Data Analyses

All data analyses were performed by the statistical package of SPSS 25 (IBM Corp., Armonk, NY, USA). First, reliability analyses were performed to investigate the psychometric properties of the HKCPE. Second, profile of participants' responses on each item was examined. Third, a correlational analysis was conducted to examine the correlation coefficient between parental expectation and age. Finally, several one-way between-subjects analyses of variance (ANOVAs) were conducted to examine the differences in parents' expectation on children's future in relation to different conditions of socio-demographic variables including parental role, educational achievement, employment status, and family income.

FINDINGS

Reliability analyses showed that the Cronbach's alpha of the HKCPE was .92, suggesting good internal consistency among the items. In addition, item-total correlation coefficients ranged between .31 and .66 and the mean inter-item correlation was .35. These findings suggest good reliability of the 24-item HKCPE used in the present study.

Profile of Responses

As shown in Table 1, except for three items (item 12, 13, and 15), other 21 items had a mean score over 4 on a 5-point rating scale, suggesting that Hong Kong Chinese parents considered most of the listed qualities important in children, reflecting a relatively conventional expectation on offspring's future. Over 70% of the participants considered the respective expectations important on 20 items. For example, over 95% of the respondents rated "be able to distinguish between right and wrong," "respect the elders," and "have a sense of responsibility" as important. For the four exceptions (i.e., item 12, 13, 17, and 24), 34.27%, 56.14%, 50.64%, and 66.80% of the participants considered "not involve in politics," "be an ordinary person," "have a good social status," and "pursue equality" important, respectively. These findings indicate that while Chinese parents in Hong Kong generally hold a conventional expectation on most aspects, they had diverse views on children's involvement in politics, being exceptional, having a good social status and equality.

Socio-Demographic Correlates

First, Person correlational analysis showed that parents' expectation was significantly correlated with age ($r = 0.08$, $p < .001$, $r^2 = 0.006$), suggesting that parental expectation was more conventional and higher if the parent was older.

Second, results of several one-way ANOVAs indicated the significant effects of the demographic variables on parents' expectation (F ranged between 6.47 and 29.42, $ps < 0.001$, see Table 2). Post-hoc comparisons using the Least Significant Difference (LSD) test were further performed to investigate how parents differed from each other in their expectation with regard to different demographic conditions.

For parental role, mothers ($M = 4.30$, $SD = 0.45$) held a more conventional and higher expectation on children's future than did fathers ($M = 4.23$, $SD = 0.47$, $F = 29.42$, $p < 0.001$, see Figure 1).

*** $p < 0.001$.

For educational achievement, parents with the lowest level (i.e., primary school or below) had a highest score ($M = 4.35$, $SD = 0.56$), suggesting a most conventional parental expectation among them. In contrast, parents with the highest educational achievement (i.e., graduate school or above) scored lowest ($M = 4.19$, $SD = 0.45$), suggesting that these parents held a least conventional expectation. Parents who completed junior ($M = 4.28$, $SD = 0.48$) or senior secondary ($M = 4.27$, $SD = 0.47$) school, matriculated ($M = 4.30$, $SD = 0.41$), or completed university education ($M = 4.26$, $SD = 0.39$) did not significantly differ from each other in their expectations on children's future (see Figure 2).

Figure 1. Parental expectation as a function of parental role.

Figure 2. Parental expectation as a function of parents' education level.

Figure 3. Parental expectation as a function of parents' employment status.

Figure 4. Parental expectation as a function of family monthly income (\$HK).

With regard to employment status, participants working full-time had the least conventional expectation, with their mean score ($M = 4.23$, $SD = 0.44$) significantly lower than that of participants working as full-time homemaker ($M = 4.31$, $SD = 0.43$), being retired ($M = 4.36$, $SD = 0.53$), or receiving social security allowance ($M = 4.36$, $SD = 0.53$). In contrast, participants who were retired or social security recipients had the most conventional expectation as they scored significantly higher than parents with other types of employment status (see Figure 3).

For family income, parents with lowest family monthly income (i.e., less than HK\$4,000) scored highest ($M = 4.46$, $SD = 0.46$), indicating that they had the most conventional parental expectation. For parents having other levels of family monthly income (all above HK\$4,000), there were only minor or insignificant differences in their expectations on children's future (see Figure 4).

DISCUSSION

The present study represents a pioneer attempt to examine the profile of responses and demographic correlates of Hong Kong Chinese parents' expectations on children's future. There are several strengths of the present study. First, this study investigated parental expectations in a sample of Chinese population, who constitute one-fifth of the world's population but have been under-researched in related fields [15]. Second, the culturally-sensitive measurement tool on parental expectations used in the present study took into account values and beliefs embedded in both Chinese and Western cultures. This ecological approach adds great value to the existing literature on parenting in Hong Kong which commonly ignored the influence of Western values [19]. Third, instead of focusing merely on parents' educational expectation for children, the present study looked at parental expectations from multiple aspects including economic, familial and social dimensions. Such a comprehensive investigation helps delineate a holistic profile of Chinese parents' expectations on children's future in Hong Kong.

Generally speaking, Hong Kong Chinese parents perceived that most of the expected achievements and qualities (e.g., establishing family, successful career, and virtues) were important, reflecting a conventional and relatively high expectation regarding children's future. For instance, over 70% of the parents treated "successful career", "competitiveness" and "completion of university study" as important for their children, echoing the general consensus that Chinese parents place great importance on children's academic achievement [28, 29]. Furthermore, over 90% of the parents highly expected morality, politeness, honesty, responsibility, and social skills in their children. Noteworthy, these qualities can be regarded as features of a "virtuous person" stressed by Confucianism, suggesting that parents' socialization goals are consistent with core Confucian values. Basically, our observation is consistent with a recent finding that poor Chinese parents in Hong Kong had high expectation toward children's education, fulfillment of family obligation and behavior [20]. These findings together echo the famous Chinese saying about parental expectation: "*wang zi cheng long*" ("hope that children will become outstanding and successful persons").

However, parents' diverse views toward some aspects of children's future should also be noted. First, although most parents expected their children to become good, well-educated and successful persons, nearly half of the parents did not consider "a good social status" as important for children. This appears inconsistent with a finding in another Confucian Heritage Culture society, South Korea, where parents had high expectations as well and strongly emphasized on their children's academic achievement as a means to gain wealth and higher social status [30, 31]. One possible reason of the present finding is that Hong Kong Chinese parents see that attainment of wealth and high social status are very stressful for their children. As a result, they tend to place less emphasis on the importance of high social status.

Second, over 65% of the parents did not mind children's involvement in politics and agreed that "pursuit of equality" was important. At the same time, "pursuit of justice", "respect for human rights" and "respect for the rule of law" in children were endorsed by the majority of the parents. These findings imply that a considerable proportion of Chinese parents in Hong Kong are open to Western liberal thoughts that value equality, democratic and young people's voice in social issues including political issues. Recently, other scholars also noticed that Hong Kong Chinese parents may adhere to both Chinese and Western values in childrearing and parenting actions [7, 27]. However, nearly 35% of the parents thought that not engaging in politics is important. This may be due to the fact that involvement in politics might be harmful to young people when we look at Chinese history in the past century.

Regarding demographic correlates, several observations could be highlighted. First, parental expectation was positively correlated with parents' age, indicating that younger parents imposed more unconventional expectations on their children. Besides, parents who were retired reported most conventional and highest expectations, which is related to the age effect as the retired parents should be older. Similar to our findings, a recent study reported that younger generations of parents in Hong Kong adopted love and nurturing parenting beliefs more than the older generations, suggesting a changing conception of childrearing and parental goals [27]. As the present study is the first one that directly relates parental expectations to their age, the finding should be tested in more studies in future.

Second, mothers' expectation was higher than that of fathers. This appears to be inconsistent with Tocu's finding that fathers had stronger traditional attitudes toward childrearing in Romania [21]. However, the present finding is in line with the result of one previous study in Hong Kong which found that Chinese mothers scored higher than did fathers on parental expectations of children's future [20]. Mothers' higher expectations echo the shift of a traditional thesis from "strict fathers and kind mothers" to "kind fathers and strict mothers" [32]. One possible explanation is that Chinese mothers have been playing a more and more salient role in taking care of and educating children in family [20], which shapes the mothers to have higher expectations on children.

Third, parents with lower educational achievement or lower family income had more conventional parental expectations such as higher expectation on children's educational, career, and familial achievement. A related finding is that social security recipients, who are supposed to have low family income, reported higher expectations on children's future. Our finding seems to be in line with Tocu's observation that parents with a lower education level had stronger traditional childrearing beliefs [21]. However, these findings are inconsistent with a recent study conducted in mainland China reported that parents with lower social economic status had lower expectations for their children [29]. Previous research in other cultures ALSO showed that parental educational expectation for children was positively associated with parents' own education level and family income [23-25]. Given the equivocal findings, future research needs to directly compare the associations between parental expectation and parents' education level and income in different cultures.

While the present study is pioneer in nature, it has several limitations. First, a quantitative research design was used. As the quantitative findings obtained in the present study are not able to reveal in-depth subjective feelings behind the numbers, such as why some parents did not value social status in children, future research should apply mix-methods design consisting of both quantitative and qualitative methodologies. Second, although Hong Kong represents a unique Chinese community and it is of great importance to examine parental

expectations in Hong Kong, it is necessary to conduct related research in other Chinese communities to enhance the universality of the present findings. Besides, it will be illuminating to compare findings obtained in different Chinese communities and reveal potential differences. Third, the present study only considered parents' gender but not children's gender. Although it is traditionally believed that Chinese parents put higher expectations on sons, there is empirical research failed to identify such a gender effect in Macao [33]. Another study even identified unexpected higher parental expectation on daughters in Mainland China [29]. Concerning the inconclusive findings, it will be interesting to directly compare parental expectations on boys and girls in Hong Kong and other Chinese societies. Nevertheless, together with other papers generated from this project [34, 35], this research project promotes our understanding of parenting expectations in Hong Kong.

Chapter 309

GENDERED EXPECTATION TOWARDS SONS AND DAUGHTERS IN CHINESE PARENTS IN HONG KONG

ABSTRACT

Based on the responses of 5,707 parents, this pioneer study examined Chinese parents' expectations about sons and daughters using the 12-item Chinese Parental Gendered Expectations for Sons and Daughters Scale (PGE). Results showed that the PGE was internally consistent. An examination of the profiles of responses to the items of the scale showed several observations: a) a significant proportion of parents held traditional expectations about sons and daughters; b) differentiation of expected parental roles in taking care of sons and daughters still persisted; c) traditional gendered expectations about sons and daughters were gradually changing. Results also showed that fathers and mothers did not significantly differ from each other regarding their gendered expectations about sons and daughters. However, lower educational level, occupational status in terms of engagement in non-full-time work, and low family income were associated with parents' higher endorsement of traditional gendered expectations about sons and daughters.

INTRODUCTION

Parental expectation reflects the objective and requirement parents set for rearing children [1]. It entails significant implications for children's development. Studies showed that parents' expectation influences parenting attitudes, mediates parenting style, and shapes children's academic performance, psychosocial competence and developmental trajectories [1-4]. In Chinese culture, parental expectation has often been discussed with gender, i.e., sons versus daughters, the reason of which may be ascribed to the deeply ingrained gender ideology that women are inferior to men. According to Shek and Sun [5], this gender inequity has its social and cultural roots. In agricultural society, men naturally occupied the dominant position as they had more physical strengths and advantages in social production. As a result, men within the family usually had greater say and more authority in handling family matters, including child-rearing matters. Women, on contrary, became dependent on men to gain status, power and wealth [5]. From a cultural perspective, the ethics of Confucianism, which have prevailed China for more than two thousand years, advocate a submissive role of women to men and code of conduct women should obey [5-7]. The inferiority of women is well reflected in traditional Chinese sayings such as, "*nan zhu wai nü zhu nei*" ("men are breadwinners and women are homemakers") and "*nü zi wu cai bian shi de*" ("innocence is a virtue for women").

Against this social and cultural background, Chinese societies have been well documented with the gender ideology of son preference, together with social phenomena such as sex-selected abortion and sex-ratio imbalance [8-11]. An extensive review of literature reveals three observations. First of all, gender-stereotypic expectations are intrinsic to the socialization from parents which are often defined by traditional gender traits and identities [10, 12, 13]. For example, Liu's [13] study indicated that parents considered it critical to cultivate masculine characteristics for sons (e.g., strong, manly and ambitious) and feminine characteristics for daughters (e.g., gentle, considerate and sentimental). Higher socio-economic families seemed to adopt a more gender-neutral approach but did not go too far. Her findings were somewhat echoed by Ge's [12] study, which also suggested that Chinese parents largely expect the masculine characteristics (e.g., humorous, athletic, independent and creative) for sons, but both masculine and feminine characteristics (e.g., kind, independent, neat and creative) for their daughters. However, as Ge [12] argued, there were still noticeable features of gender stereotype, suggesting a relative stability of gender ideology. According to Sadker [14], these gender stereotypes can underestimate daughters' potentials and restrict their career choice.

Second, research shows a contradictory picture of parents' educational expectation for sons and daughters. Some researchers claimed that sons received higher educational aspirations from parents and bore more pressure, especially in rural areas of China [9, 10, 15]. In a study carried out in rural region of Gansu, one of the most impoverished regions in China, findings suggested higher maternal aspirations for boys (although the aspirations for girls were also high) and that girls were more likely to be called on for household chores [10]. The higher expectation was well reflected in practice that more domestic resources were invested in sons' schooling, which resulted in lower educational attainment of rural girls [11, 16].

Nevertheless, different voices also emerged where researchers argued no son preference in terms of parents' educational expectation [17-20]. For example, two recent studies [18-19] suggested that parents in fact held higher expectations for daughters for their secondary education, indicating a major improvement of gender ideology. This improvement for girls, asserted by many scholars, was an unintended consequence of Chinese one-child policy [18, 20] and the upheaval of society in the past few decades where younger generations of women had played a more active social role than ever before [7, 12]. It is also noted that most of these studies were conducted in more developed regions in Greater China. As Wang [11] argued, "children who live in urban areas with educated parents received better educational opportunities and experience less gender bias" (p. 3). Obviously, there are urban-rural differences in gendered expectations for sons and daughters in China.

Third, the favor of sons is highly associated with family responsibility. Research provides empirical evidence that in many regions, especially rural China, parents still expected their sons to provide support to them in their old age [6, 10]. This perspective gave rise to parents' beliefs that educating girls was a waste [10]. This pragmatic attitude was prevalent in families with limited resources who hoped to seek the maximum return of educational profits [21]. In addition, parents might feel obliged to shoulder the financial responsibility of their sons' marriage, making investment within a family even more tilted towards sons [22]. This expectation stems from the traditional agricultural society where daughters would leave the family after marriage, which means a loss in manpower. As a result, investment in daughters is comparatively less because they will become "outsiders" after marriage.

To sum up, the aforementioned literature indicates a general perpetuated gender differentiation in the light of parental expectation. Interaction effects were also found between geography, SES, generation, education and gender. Therefore, parents' expectations towards sons and daughters should be understood in specific sociocultural contexts. The focused context of our study, Hong Kong, is a unique place in terms of culture and society. On one hand, Hong Kong is a Chinese society with Confucian ethics and patriarchal norms permeating every aspect of society, including unequal gender role positioning [23]. Furthermore, Buddhist and Taoist thoughts also highlight the importance of men to women. On the other hand, it embraces Western cultural values to a larger extent than other communities in Mainland China, as it had been a British colony for over a century. The rapid social and economic development has led to a more favorable status of women. Recent statistics [24] show that female students have outnumbered male students in UGC-funded undergraduate (54.6%) and taught postgraduate programmes (62.5%), and reached 41.9% in research postgraduate programmes. In career field, women professionals such as Certified Public Accountant and lawyers have witnessed a continuous increase in the past decade [24], which all suggests a more equal gender status in Hong Kong.

Despite such a unique blend of Eastern and Western cultures in Hong Kong society, there is a scarcity of research that has attempted to explore parents' gender perspectives towards child rearing. As a response, we fill a gap in the literature by systematically examining Hong Kong Chinese parents' expectations towards sons and daughters. The present study draws on a culturally-sensitive measurement tool and includes various demographic correlates in the analysis. There are several objectives of this study. First, we attempted to examine the reliability of an indigenous developed measure of parental expectations about sons and daughters in a large sample of Chinese parents in Hong Kong. Second, we investigated the profile of responses to the items in the indigenous scale. Finally, socio-demographic

correlates of parental expectations about sons and daughters, including parental gender, education level, occupation status and family income were examined.

For the socio-demographic correlates, several hypotheses were proposed. For age, before of cohort effect (i.e., older people are more susceptible to traditional influences), it was predicted that age would be negatively related to gendered expectations about sons and daughters. On the other hand, because the Western influence and Hong Kong is quite a gender-equal society, it was expected that there would not be difference between fathers and mothers on the gendered expectations about sons and daughters. Regarding the educational and income correlates, it was expected that higher education background (hence higher family income) would be associated with a weaker endorsement of traditional gender stereotype expectations.

OUR STUDY

Ethical approval for this study was obtained from the “Survey and Behavioural Ethics Committee” at The Chinese University of Hong Kong. The participants in this study were 5,707 Chinese parents recruited from 5 out of 13 geographical districts in Hong Kong, including “Sham Shui Po”, “Wan Chai”, “Yau Tsim Mong”, “Northern”, and “Eastern Hong Kong Island”. The participants were recruited through the method of quota sampling to comprise five generational groups who had child/children born from 1970s to 2010s. The different generational and geographical groups collectively provided a mixed socioeconomic background of the participants who were from households with high, middle, or low income. These participants were recruited through multiple methods and sources. Specifically, for the participants coming from the oldest generational group, we recruited them through NGO service centers for elders, research institutes for aging, and associations on parental education. For the participants whose children were born in 1980s and 1990s, we recruited them through secondary schools, higher education institutions, NGOs and the Internet. For the participants who had children born in 2000s and 2010s, we recruited them through kindergartens and primary schools.

Among the final sample, around one third of the participants were men (31.7%) and two thirds were women (67.5%). The age scope of the participants was wide, ranging from 20s to 90s. Around half of the participants had two children and one third of them had one child. Less than one third of the participants had completed college or university education (24.2%) whereas a much smaller proportion of them completed postgraduate education (4.7%). Participants’ detailed demographic profile can be found elsewhere [25].

Instruments

The participants completed a questionnaire including demographic information and four scales measuring “Parental Expectations for Children”, “Parental Gendered Expectations for Sons and Daughters”, “Parental Roles”, and “Parental Beliefs”, respectively. In the present study, we focused on profiles of the “Parental Gendered Expectations for Sons and Daughters” (PGE here after) and related demographic correlates. The PGE scale contained 12

items outlining traditional parental expectations for sons and daughters, such as “sons are more responsible than daughters”, “sons are in greater need of ability to bring home bacon than daughters”, and “marriage is more important than a career to daughters”. A five-point rating scale (1 = “strongly disagree” and 5 = “strongly agree”) was applied with a higher score representing a more traditional gendered expectation for sons and daughters. The scale showed good internal reliability in this study with the Cronbach’s alpha of 0.90 and the mean inter-item correlation of 0.43.

The demographic information measured the socio-demographic characteristics of the participants, including gender, parental role (i.e., father or mother), age, educational level, occupational status, and total family income.

Data Analyses

We conducted the following analyses. First, we examined the reliability of the scale in terms of internal consistency. Second, we computed the percentage of positive or negative responses for each item to form the response profiles. Third, we conducted correlation analysis to examine the linkage between participants’ age and their gendered expectation for sons and daughters. Finally, several one-way ANOVAs were performed to see whether parents’ gendered expectations for sons and daughters could be related to different demographic factors including parenting role, educational level, working condition, and family income.

FINDINGS

Reliability analyses showed that the scale was internally consistent (Cronbach’s alpha = 0.90), with acceptable mean inter-item correlation (0.43) and mean item-total correlation (0.62).

Table 1 shows participants’ responses on each item. For 10 out of 12 items, a significant proportion of the participants (between 27.8% and 49.5%) gave positive responses which represent their endorsement of the traditional parental expectations for sons and daughters. For the two exceptional items (Item 6 and Item 12), over half of the participants (between 55.0% and 57.3%) endorsed the respective traditional gender beliefs about sons and daughters.

More specifically, for parents’ differentiated expectations towards sons and daughters (Items 1-3), over one third of the parents expected that “sons are more responsible than daughters” (34.9%), “sons are more capable of supporting the family” (48.7%), and “sons have stronger leadership than daughters” (34.6%). Regarding parental responsibilities and practices towards sons and daughters (Items 4, 9, 10, and 12), parental belief appeared to shift from “parents should always take care of children” as less than 30% of the parents thought that “parents must help sons to get married and establish family” (Item 4). However, 46.5% and 57.3% of the parents had an expectation that “father takes a more important role in educating sons” (Item 9) while “mother take a more important role in educating daughters”

Table 1. Profile of responses (N = 5,490-5,635)

I expect my children to	Mean	SD	1		2		3		4		5		Positive response (options 4-5)	
			Strongly disagree		Slightly disagree		Neutral		Slightly agree		Strongly Agree		N	
			N	%	N	%	N	%	N	%	N	%	N	%

女兒會嫁得出 Daughters are able to get married	3.49	1.18	450	8.0	498	8.9	1,878	33.6	1,401	25.0	1,368	24.5	2,769	49.49
女兒斯文，賢淑 Daughters are decent and virtuous	3.63	1.08	262	4.7	423	7.6	1,826	32.7	1,707	30.6	1,367	24.5	3,074	55.04
如果女兒太能幹，會難找伴侶 If daughters are too capable, it will be difficulty for them to find a partner.	2.91	1.24	1,014	18.1	916	16.4	1,862	33.3	1,181	21.1	618	11.1	1,799	32.18
對女兒來說，婚姻比事業成功更重要 A marriage is more important than a successful career to daughters.	3.08	1.20	753	13.5	811	14.5	2,024	36.2	1,233	22.1	766	13.7	1,999	35.78
父親在教養兒子方面的角色比較重要 Father takes a more important role in educating sons.	3.35	1.19	530	9.4	670	11.9	1,799	32.1	1,514	27.0	1,096	19.5	2,610	46.53
我對兒子管教比對女兒嚴厲 Compared to daughter, I discipline my son much more rigorously.	2.88	1.25	1,089	19.5	811	14.5	2,004	35.9	1,045	18.7	634	11.4	1,679	30.07
可以的話希望能有個兒子 if possible, I wish to have a son.	2.93	1.32	1,160	21.1	638	11.6	1,972	35.9	875	15.9	845	15.4	1,720	31.33
母親在教養女兒方面的角色比較重要 Mother takes a more important role in educating daughters.	3.61	1.17	427	7.6	430	7.7	1,535	27.4	1,748	31.2	1,466	26.2	3,214	57.33

(Item 12), respectively. Besides, some parents (30%) reported that they disciplined sons much more rigorously. With reference to gender beliefs for daughters (Items 5-8), nearly half of the parents expected their daughters to get married (Item 5) and 55% of them expected their daughters to be decent and virtuous (Item 6). Besides, 32.2% of the participants held a view that “it will be difficulty for daughters to find a partner if they are too capable” (Item 7). Likewise, 36.8% of them regarded a marriage as more important than a successful career to their daughters (Item 8). Finally, 31.3% of the participants reported that they “wish to have a son if possible” (Item 11), indicating that nearly one third of the parents held traditional son preferences.

Based on the response profiles outlined above, it appeared that while most Chinese parents in Hong Kong generally did not show extreme gendered expectations towards their children, some parents still held gender stereotypical attitudes towards sons and daughters.

Regarding socio-demographic correlates of gendered expectations towards their children, the correlational analysis showed that parents' expectation for sons and daughters was significantly and positively associated with their age ($r = 0.24$, $p < .001$, $r^2 = 0.06$), meaning that the older the parents are, the more likely they hold a traditional gendered view towards sons and daughters.

Table 2. One-way ANOVAs

Variables	N	Mean	SD	F	η_p^2
Parental role				0.15	0.00002

≥80,000	682	2.87	0.79		

*** $p < 0.001$.

Second, as shown in table 2, parental role did not show a significant effect on parents' different expectations for sons and daughters ($F = 0.15$, $p = 0.70$), suggesting that fathers and mothers did not differ significantly in their gendered expectations for sons and daughters

(also see Figure 1). Different from parental role, educational achievement ($F = 94.42, p < 0.001, \eta^2_p = 0.08$), occupational status ($F = 54.13, p < 0.001, \eta^2_p = 0.05$) and family income ($F = 44.60, p < 0.001, \eta^2_p = 0.06$) served as significant predictors.

Figure 1. Parental gendered expectation towards sons and daughters as a function of parental role.

Further comparisons employing the LSD (“Least Significant Difference”) test indicated that parents’ score on gendered expectations for children decreased as their educational achievement increased (see Figure 2). Specifically, parents with primary school or below levels of education (i.e., the lowest education achievement) had a highest score of gendered expectations for children ($M = 3.61, SD = 0.89$), indicating a most traditional and gender stereotypical view towards sons and daughters among these parents. Parents who completed education at junior secondary school level showed the second highest mean score ($M = 3.31, SD = 0.83$), followed by the scores among parents having education at senior secondary ($M = 3.10, SD = 0.81$) or matriculated levels ($M = 3.12, SD = 0.85$), which were significantly higher than the score of parents who completed university/higher education ($M = 2.94, SD = 0.78$). Finally, parents had the highest level of education (i.e., graduate school or above) showed the least gender stereotypical expectations for sons and daughters as reflected by their lowest mean score ($M = 2.94, SD = 0.78$).

Figure 2. Parental gendered expectation towards sons and daughters as a function of parents’ education level.

Referring to parents’ occupational status, respondents who had full-time jobs showed the lowest mean score ($M = 4.23, SD = 0.44$), indicating their least traditional expectations for sons and daughters. Compared with these respondents, parents who had part-time jobs, or worked as full-time homemakers, or did not find a job had significant higher mean scores (M

ranged between 3.12 and 3.14). As depicted in Figure 3, parents who had been retired or living on social assistance scored the highest (M ranged between 3.46 and 3.56) and held the most traditional different expectations for sons and daughters.

Figure 3. Parental gendered expectation towards sons and daughters as a function of parents' employment status.

Figure 4. Parental gendered expectation towards sons and daughters as a function of family monthly income (\$HK).

Based on Figure 4, there is an obvious trend that parents' mean scores on gendered expectations for sons and daughters decreased as their family income increased. For example, parents who earned the highest monthly income (i.e., more than HK\$80,000) showed the lowest mean score ($M = 2.87$, $SD = 0.79$), suggesting that these parents upheld the least traditional and gender stereotypical expectations for their children. In contrast, parents who had lowest level of monthly income (i.e., below HK\$4,000) demonstrated the most traditional gendered expectations for sons and daughters indicated by the highest mean score ($M = 3.65$, $SD = 0.97$) (see Figure 4).

DISCUSSION

This pioneer study attempted to investigate the profiles of responses of Chinese parents' gendered expectations for their sons and daughters in Hong Kong as well as how their

traditional beliefs for sons and daughters were associated with demographic variables such as parental role, educational achievement, and family income. Generally speaking, the majority of Chinese parents in Hong Kong have changed their traditional gender stereotype towards sons and daughters in terms of differential expectations and parenting practice for sons and daughters. Yet, there are still some parents who held traditional gender views in some aspects such as son preference and importance placed on daughters' characteristics related to female gender role of home maker. In conjunction with other empirical findings [7, 22], our observations in this study suggest that while some traditional family and gender values have been changing gradually in Chinese communities with the influence of rapid social transitions and economic development, some traditional Chinese beliefs about sons and daughters still have place in the contemporary society [26].

Several observations could be highlighted from the present findings. First, traditional gendered expectations about sons and daughters were gradually changing. For instance, only around one third of parents expected sons to be more responsible and to have stronger leadership than daughters. As these qualities can be regarded as gender traits associated with men's traditional social role of resource providers as well as their superiority to women, this observation suggest that Chinese parents' socialization goals may have shifted away from the traditional Chinese gender ideology that "*nan zhu wai nü zhu nei*" ("Men are breadwinners and women are homemakers"). This speculation is consistent with the fact that in the past several decades, women have substantially participated in the labor market and provided financial support for the family through having full-time jobs [26]. Echoing this finding, shifts in parents' traditional gender beliefs for daughters were also observed. Specifically, around two thirds of parents did not agree that daughters' capability would hinder their intimate relationship, which appeared to be inconsistent with Chinese traditional belief that "*nü zi wu cai bian shi de*" ("innocence is a virtue for women"). Likewise, more than 60% of the parents tended not to regard daughters' marriage as more important than career, suggesting that parents placed more importance on daughter's career success than before. These findings are in line with previous conclusion that Chinese women have been encouraged to pursue educational and career opportunities and take other responsibilities than merely being housewives [7, 24].

Second, it is notable that a considerable proportion of parents still held traditional expectations for sons and daughters. For example, nearly half of parents still expected their sons to be more capable of supporting family and their daughters to get married. Besides, over half of parents expected their daughters to have feminine characteristics such as decent and virtuous that are considered important for women to fulfill their responsibilities in looking after family and attending to children. Besides, nearly one third of parents indicated their willingness to have a son, which reflected their traditional son preference. These findings indicate that traditional Chinese beliefs and gender ideology still affect parental expectations for sons and daughters in some aspects to a certain extent despite the increasing gender equality. This is consistent with Ge's [12] suggestion that gender ideology is relatively stable and noticeable gender stereotypical features still exist in Chinese society. The finding is also in accordance with the picture that parents imposed higher educational aspirations for sons than for daughters and devoted more resources to sons' schooling while required daughters to assist more with household chores [10-11].

The third observation is that differential parental roles in taking care of sons and daughters still persisted. Particularly, more than 46% of parents assumed fathers' greater

responsibilities in educating sons whereas over 57% of participants advocated the more important role of mothers in educating daughters. Noteworthy, different parental roles of fathers and mothers are largely attributable to their culturally prescribed gender roles in family. Traditionally, men bear obligations to secure family income and maintain family honor whereas women are responsible for “interior chores” (i.e., “*nan zhu wai nü zhu nei*” mentioned before). This gender expectation makes a Chinese father the more appropriate educator and role model in family to discipline sons who are expected to be a qualified father one day and further expand the reputation of the family lineage [27]. Likewise, a mother in family is more likely to be a role model for daughters in everyday parenting practice. Such differentiated parental roles of fathers and mothers in educating sons and daughters can be reflected in well-known idiomatic Chinese expressions such as “*yang bu jiao, fu zhi guo*” (to feed but not teach the child, the father’s fault indeed”) and “*fu zi zhi yan, bu ke yi xia*” (“the father should be strict with the son and not improperly close”).

Apart from the above mentioned findings, this study also delineated associations between demographic variables and Chinese parents’ expectations for sons and daughters. First, fathers and mothers did not significantly differ from each other in their expectations. This finding is consistent with previous evidence that differences between paternal and maternal perceptions of the ideal child in Hong Kong were minimal [28]. A more recent study also reported that women in general were as traditional as men regarding their attitudes towards gender roles [7]. This finding shows that paternal and maternal expectations about sons and daughters are not much differentiated in contemporary Hong Kong. Third, older parents showed greater adherence to traditional expectations for sons and daughters. Echoing this age effect, retired parents who were older reported a higher level of traditional gender stereotypical attitudes towards sons and daughters. Again, this finding is in line with Hu and Scott’s [7] observation that younger women were less traditional than their senior counterparts towards gender values. The significant effect of age is probably a reflection of cohort effect.

Third, consistent with previous studies on demographic correlates of parental beliefs and practice [7, 29], we found that higher educational level, employment with full-time work, and higher family income were linked with less traditional expectations and attitudes towards sons and daughters. The findings are consistent with a general expectation that social and economic development enables endorsement of less traditional attitudes towards gender values and gender equality [26].

Despite the above important findings revealed by the present study, several limitations are noted. First, this study is quantitative in nature which is unable to inform subjective perceptions underlying the quantitative results. For example, we do not know what factors and possible mechanisms make some parents not see daughters’ marriage as more important than career. Thus, to portray a holistic picture about parental expectations for sons and daughters, both quantitative and qualitative research methods should be applied in future research. Second, geographic influence on traditional beliefs has been identified [7]. As Hong Kong is a very urbanized city, it will be insightful to compare parental expectations for sons and daughters in different regions in Greater China. Finally, the present study investigated the demographic correlates to parental expectations towards sons and daughters while not taking into account the influence of other psychosocial factors, such as beliefs of collectivism or individualism and self-identity. Future research should include rich influential variables.

Nevertheless, the present study adds value to the existing literature and advances our knowledge of Chinese parents' expectations for sons and daughter in Hong Kong.

ABSTRACT

In this chapter we report on an investigation into the family division of labor among Chinese parents in Hong Kong and its association with gender, educational level, occupational status and family income. It drew on a culturally sensitive scale developed for the people under studied. A total of 5,707 questionnaires were included in the analysis, and respondents showed a diversity of demographic characteristics. Analyses of the profiles of responses showed a persistence in gendered share of childcare responsibilities with mothers playing the main role in childcare and fathers playing an assisting role, although a more equalitarian gender attitude was noticed. Regarding other socio-demographic correlates, it was found that parents' educational level, intensity of market work, and family income in general were negatively correlated to the participation in childcare duties, a possible explanation of which was time availability. Endorsement of traditional gender stereotype was also related to the background socio-demographic factors.

INTRODUCTION

Gendered division of labor has been widely studied in Western societies. The higher level of women employment has been witnessed with a slow course towards an equal share of

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

housework [1]. Women still tend to undertake the majority of housework and parenting routines [2]. On the other hand, a more equal share of child rearing duties has many benefits. Positive father's involvement is associated with children's wellbeing, as it decreases children's problem behaviors and facilitates their cognitive and linguistic development [3-6]. It is also highly related with marital satisfaction, although a complex picture has been presented across cultures [7, 8]. However, gendered division of labor has been an understudied field in Hong Kong. Against this background, the present study adds to the scientific literature in the field in two notable ways. First, it draws on a culturally sensitive scale to study division of labor in the local context. Second, as few researchers have specifically examined how division of labor interacts with socio-demographic factors as standalone factors besides gender, this study includes educational level, occupational status and family income in the analysis.

There has been a considerable body of literature focusing on gender inequality in sharing childcare duties with reference to factors such as policy, socioeconomic status and gender perception in Western societies. In general, the extant literature suggests a persistence in gendered division of labor in parenting, with mothers undertaking more intensive parenting while fathers taking a back seat, despite the fact that fathers are seen with increased participation in childrearing and other household responsibilities [9-14].

From a macro level, researches have specifically looked into social policy and gender norms and perspectives [14-17]. Most studies have found positive effect of family-friendly social policies such as supportive leave policy and flexible work arrangements on promoting gender equality in childcare and supporting work-family reconciliation [16, 18-20]. However, some studies have raised doubts about the extent to which the policy can be translated into practice. For example, Windebank [14] argued that in French society, the social policy aiming at promoting gender equality in domestic matters had limited effect in that it helped women reconcile work-family conflicts but failed to encourage or coerce men, or take care of the social feedback for them to engage more in childcare. Indeed, supportive non-parental childcare, as argued by Craig and Powell [15], did relieve mothers of childcare responsibilities to some extent. However, it was accompanied by the additional time devoted to paid work and higher subjective time pressure, while "fathers' time is more constant" (p.100). Therefore, they argued for a more father-friendly policy instead.

The gender perspective has been perceived as an important underlying reason to explain gendered division of labor at home [14, 21]. An egalitarian gender attitude very often predicts a more equal share of responsibilities [16, 22], but it presents a complex picture as it interplays with many other factors. Highly educated parents are often more receptive to progressive gender norms and have better understanding of proper childcare [9]. In a quantitative study of highly educated, dual-earner household in Spain, Martínez and his colleagues [23] found these parents tended to agree more with egalitarian gender roles in parenting. The factors of country and culture are also at play. For example, in a study of gender attitudes conducted by Buber-Ennsner and Panova [24], substantial variation was found among 14 European countries, Australia and Japan in terms of level of traditionalism. To be specific, Norway and Estonia held the most egalitarian view towards mother's role in childcare, while Hungary, Georgia and Russia held the most conservative view, for which the researchers postulated that the diversity could be ascribed to influences such as provision of public childcare, maternal leave, religion and culture.

From a micro level perspective, parent's educational level, income or work status have been a focus of concern [9, 12, 25, 26], although researchers did not always distinguish housework from childcare duties. Käsäälä and Oinas [26] carried out a study on dual-career couples ("career" was defined as performing professional or managerial work) in Finland who had higher educational level, work status and earning capacity. They found that dual-career couples assumed more equal responsibility in domestic division of labor than no-career parents, male-career couples and female-career couples did, which might be attributed to the limited time availability of dual-career women, or their likelihood to outsource or bargain their way out of unpaid domestic housework. Heisig's [12] quantitative study involving 33 countries echoes Käsäälä and Oinas' [26] findings to some extent, as it also revealed that household income found its expression in housework time. High-income couples devoted less time in housework than their low-income counterparts, and the contrast was even starker for women. Differed from these arguments based on the economic perspective, Craig [9] argued for a contradictory effect amongst educational level, earning capacity and time spent with children. In fact, her research provided empirical evidence that university-educated parents had higher receptivity to attentive child rearing and allocated more time to care of children, the effect of which outweighed the effect of a pull to the market. Her findings are consistent with a prior study conducted by Sundström and Duvander [27] in Sweden. Drawing on parental leave as a proxy for time for childcare, they found that both fathers' and mothers' income and educational level were positively associated with paternal leave use.

As can be seen from the above review of literature, the division of labor in childcare presents a complicated picture with sometimes contradictory results [28, 29]. Admittedly, participation in childcare is often conditioned by many different forms of social influences, and therefore cannot be easily generalized across countries and cultures. As argued by many researchers [30-32], cultural sensitivity should constitute a pivotal part in the study of parenting and always reflect culturally-appropriate values and beliefs.

Most of the related studies in the field have been carried out in Western contexts. Only a few studies have been conducted to examine how participation of housework duties interplays with social variables in mainland China [33, 34]. Overall, a gendered division of labor was found in these studies, with a conformity to traditional gender norms that women undertook the major housework and childcare. After all, "work-family balance is considered a woman's problem" [33]. Little research has been conducted in the context of Hong Kong.

In the traditional Chinese culture, men and women were seen to be very different. For men, as they have more strength, they are primarily responsible for farming activities. Therefore, men have more authority in agricultural society and they are leaders of the society. In contrast, women are basically responsible for domestic chores in the family and they serve as subordinate role to men. With reference to the role of men and women in the family, the husband has authority over his wife and he can divorce his wife if she does not perform well. These differences are further translated into the differential roles of fathers and mothers, where fathers are typically regarded as the leader of the family whereas mothers take up the caregiving tasks. These differences are existing in contemporary Hong Kong society [32].

Against this background, this article attempts to look at the profiles of responses of Hong Kong parents' division of labor and examine the socio-demographic correlates including gender, educational level, occupational status and family income. It draws on the Parental Division of Labor Scale which assesses three constructs: participation in childcare as the main

caregiver; participation in childcare as the assisting caregiver; attitude towards traditional gender stereotype. The research questions and hypotheses are as follows:

- 1) What are the response profiles of Chinese parents to the items in the scale?
- 2) Is there any gender difference in parental division of labor and gender belief?
 - Hypothesis 1a: Compared with fathers, mothers would be more involved as main caregivers.
 - Hypothesis 1b: Compared with mothers, fathers would be more involved as assisting caregivers.
 - Hypothesis 1c: Compared with mothers, fathers would have a stronger endorsement of traditional gender stereotypes.
- 3) Are parental division of labor and gender belief related to the educational level of the parents?
 - Hypothesis 2a: Because of work constraint, parents with higher education attainment would be less involved as main caregivers.
 - Hypothesis 2b: Because of work constraint, parents with higher education attainment would be less involved as assisting caregivers.
 - Hypothesis 2c: Parents with higher education attainment would have lower endorsement of the traditional gender stereotype.
 - Hypotheses 2d, 2e and 2f: similar expectations were proposed for spouse.
- 4) Are parental division of labor and gender stereotypes related to the occupational status of parents?
 - Hypothesis 3a: Compared with parents who committed more time to market work, parents who committed less time to market work would involve more as main caregivers.
 - Hypothesis 3b: Compared with parents who committed more time to market work, parents who committed less time to market work would involve more as assisting caregivers.
 - Hypothesis 3c: Compared with parents who committed more time to market work, parents who committed less time to market work would have stronger endorsement of the traditional gender stereotype.
 - Hypotheses 3d: Parents with spouse who committed less time to market work would involve less as main caregivers.
 - Hypotheses 3e: Parents with spouse who committed less time to market work would involve less as assisting caregivers.
 - Hypotheses 3f: Parents with spouse who committed more time to market work would have lower endorsement of the traditional gender stereotype.
- 5) Are parental division of labor and gender belief related to family income?
 - Hypothesis 4a: Family income would be negatively related to endorsement of main caregiving role.
 - Hypothesis 4b: Family income would be negatively related to endorsement of assisting caregiving role.
 - Hypothesis 4c: Family income would be negatively related to endorsement of the traditional gender stereotype.

OUR STUDY

This study is a part of the project entitled “Raising children in Hong Kong” which adopts a cultural-intergenerational perspective into Hong Kong parents’ beliefs in parental roles and responsibilities [31]. Researchers developed several scales in this project. In the present paper, we focus on division of labor in child rearing (“gendered parental roles”) assessed by the Parental Division of Labor Scale. There are five items in this scale, i.e., Item 1: In the domestic division of labor, I take charge of childcare. Item 2: In the domestic division of labor, I assist in childcare. Item 3: I am an implementer in childcare. Item 4: I am a decision-maker in childcare. Item 5: I agree with the perspective “men are breadwinners and women are homemakers”. Respondents were asked to score on a 5-point Likert scale with 1 indicating “disagree very much” and 5 indicating “agree very much”. These items assess three aspects of division of labor in the family, including whether one plays the role of main caregiver (items 1, 3 and 4), whether one plays an assisting role in childcare (item 2) and attitude towards the traditional view on family division of labor (item 5).

Missing	6.5

In total, 5,707 valid questionnaires were collected and included in the analysis. The sample included five generational cohorts of Hong Kong parents with different demographic characteristics in terms of gender, age, number of children, educational level and employment status. The profiles of respondents are shown in Table 1. Cronbach's α reaches .765 for the five items, suggesting a moderate to high reliability. In the analysis, hypotheses were tested using one-way ANOVA. For each of these three categories, this study aims to investigate the association of the scale scores with gender, educational level (of both the respondent and his/her spouse), occupational status (of both the respondent and his/her spouse), and family income.

Table 2. Division of labor by gender

	Father Mean (SD)	Mother Mean (SD)	<i>F</i>
Main role	3.18 (.92)	3.60 (.98)	224.49**
Assisting role	3.30 (1.07)	3.03 (1.24)	62.13**
Traditional belief about gender role	3.04 (1.23)	2.93 (1.28)	9.76**

** $p < .005$.

FINDINGS

Table 2 presents the descriptive statistics for the domestic division of labor in childcare by gender. Fathers reported lower scores in assuming the main role of child rearing ($M = 3.18$) than mothers did ($M = 3.60$), but higher scores in taking the assisting role (father: $M = 3.30$; mother: $M = 3.03$). Significant difference was observed for both roles (main role, $F = 224.49$, $p < .005$, $\eta^2 = .04$; assisting role, $F = 62.13$, $p < .005$, $\eta^2 = .011$). Significant

difference was also found between men and women in their degree of approval of the traditional belief that men as breadwinners and women as homemakers ($F = 9.76, p = .002, \eta^2 = .002$). In short, Hypotheses 1a, 1b and 1c were supported.

Table 3. Division of labor by educational level

	Main role Mean (SD)	Assisting role Mean (SD)	Traditional belief about gender role Mean (SD)
Primary or below	3.61 (1.06)	3.56 (1.26)	3.40 (1.40)
Lower secondary school	3.47 (1.00)	3.26 (1.23)	3.14 (1.34)
Completed secondary school	3.45 (.97)	3.10 (1.19)	2.92 (1.23)
College	3.53 (.98)	3.05 (1.14)	2.96 (1.22)
University/ Higher education	3.44 (.92)	2.90 (1.09)	2.78 (1.15)
Graduate School	3.24 (1.00)	2.69 (1.05)	2.46 (1.09)
<i>F</i>	6.39***	42.07***	37.36***

*** $p < .001$.

Table 3 indicates that participants' educational level had a negative association with involvement as main caregivers ($F = 6.39, p < .001, \eta^2 = .005$). A general decrease of mean for the "main role" was observed with the increase of educational level. Post-hoc comparisons using the Least Significance Difference (LSD) Test were conducted to identify pairs of means that differ. The result showed that the mean difference did not generate a statistical difference at .05 significant level between the groups of "lower secondary school", "completed secondary school", "college" and "university/higher education". However, the group of "primary or below" stood out with significant mean higher score in performing the main role than the rest of the groups (except for the group of "college"), while parents with postgraduate degree were the least likely to engage as the one in charge of childcare. The findings supported Hypothesis 2a. The participant's educational level was also negatively related to performing assisting role ($F = 42.07, p < .001, \eta^2 = .036$). The LSD post hoc tests revealed that the variance of mean between the groups all reached .05 significant level (except for between "completed secondary school" and "college", $p = .52$). The findings supported Hypothesis 2b. With regard to the gender belief, parents received more education scored significantly lower score on approving the gender stereotype ($F = 37.36, p < .001, \eta^2 = .032$). It is noted that the groups of "primary or below" and "lower secondary school" differed significantly from the rest four groups. The findings supported Hypothesis 2c.

Similar to the result shown in Table 3, there was significant difference between the educational level of the spouse and the respondents involving as the main caregivers (see Table 4) ($F = 4.28, p = .001, \eta^2 = .004$), as the assisting role ($F = 16.90, p = .000, \eta^2 = .019$), and the degree of agreeing with the gender stereotype ($F = 17.29, p = .000, \eta^2 = .019$). The general decreasing mean for both the "main role" and "assisting role" suggested that highly educated spouse was accompanied by less participation in childcare for the respondent. Similar association was found for the gender stereotype. The findings supported Hypotheses 2d, 2e and 2f.

Table 4. Division of labor by educational level (spouse)

	Main role Mean (SD)	Assisting role Mean (SD)	Traditional belief about gender role Mean (SD)
Primary or below	3.56 (.99)	3.39 (1.24)	3.34 (1.33)
Lower secondary school	3.44 (.99)	3.20 (1.19)	2.99 (1.27)
Completed secondary school	3.43 (.94)	3.10 (1.15)	2.93 (1.21)
College	3.38 (.97)	2.97 (1.11)	2.98 (1.17)
University/ Higher education	3.32 (.93)	2.88 (1.07)	2.75 (1.16)
Graduate School	3.35 (.93)	2.79 (1.08)	2.59 (1.11)
<i>F</i>	4.28**	16.90**	17.29**

** $p < .005$.

Table 5. Division of labor by occupational status

	Main role Mean (SD)	Assisting role Mean (SD)	Traditional belief about gender role Mean (SD)
Work full time	3.35 (.93)	2.99 (1.11)	2.75 (1.18)
Work part time	3.49 (.99)	3.02 (1.22)	2.87 (1.25)
Full time home-maker	3.63 (.97)	3.02 (1.23)	3.13 (1.23)
Unemployed or between jobs	3.56 (.96)	3.15 (1.22)	2.95 (1.37)
Retired	3.54 (1.06)	3.52 (1.24)	3.32 (1.38)
Social security recipient	3.71 (.97)	3.22 (1.29)	3.53 (1.28)
<i>F</i>	15.56***	35.10***	42.45***

*** $p < .001$.

As shown in Table 5, there were significant differences amongst the occupational groups in terms of undertaking the main role ($F = 15.56$, $p = .000$, $\eta^2 = .013$). Parents working full time scored the lowest, and post hoc LSD tests showed that it differed significantly with the other four groups (except for “unemployed or between jobs”, $p = .06$). According to the results, the four groups who committed less time to market work (i.e., “full time home-maker”, “unemployment or between jobs”, “retired” and “social security recipient”) reached higher mean scores in taking the main role in childcare than the rest two groups who devoted more time to market job (i.e., “work full time” and “work part time”). As to the assisting role, although a significant difference was found between groups ($F = 35.10$, $p = .000$, $\eta^2 = .03$), post-hoc comparisons indicated that only the group “retired” which was found with the highest score were different from the other five groups. The rest of the pairs did not generate significant difference at .05 level. Groups also varied with regard to the gender belief ($F = 42.45$, $p = .000$, $\eta^2 = .036$). The incremental mean scores suggested that more intensive workforce participation (i.e., “work full time” and “work part time”) was accompanied by higher tendency to reject this gender stereotype. Generally speaking, the findings provided support for Hypotheses 3a, 3b and 3c.

Table 6. Division of labor by occupational status (spouse)

	Main role Mean (SD)	Assisting role Mean (SD)	Traditional belief about gender role Mean (SD)
Work full time	3.46 (.94)	2.92 (1.11)	2.80 (1.16)
Work part time	3.32 (.90)	3.19 (1.10)	2.99 (1.21)
Full time home-maker	3.08 (.90)	3.32 (1.09)	3.25 (1.24)
Unemployed or between jobs	3.34 (.94)	3.07 (1.21)	2.91 (1.25)
Retired	3.41 (1.03)	3.34 (1.24)	3.09 (1.37)
Social security recipient	3.67 (.88)	3.35 (1.11)	3.56 (1.28)
<i>F</i>	12.28***	21.63***	16.56***

*** $p < .001$.

As presented in Table 6, groups differed for the three measures according to spouse's occupational status. For the main role ($F = 12.28$, $p = .000$, $\eta^2 = .013$), the status with the spouse performing as a full-time home-maker was found with the respondent scoring the lowest in assuming the main role. Post hoc tests showed the mean was significantly lower than the rest groups. However, respondents with spouse as social security recipient were very likely to take the main role ($M = 3.67$). Table 5 also shows that respondents with spouse's occupational status as "social security recipient" ($M = 3.35$), "retired" ($M = 3.34$) and "full time home-maker" ($M = 3.32$) were more likely to perform the assisting role ($F = 21.63$, $p = .000$, $\eta^2 = .024$). As to the gender perception ($F = 16.55$, $p = .000$, $\eta^2 = .018$), it saw the least acceptability among respondents with spouses working full time ($M = 2.80$), and the most ($M = 3.56$) among those with spouses as social security recipient. In general, the findings did not give strong support to Hypotheses 3d and 3e, but confirmed Hypothesis 3f.

Table 7. Division of labor by monthly family income (HKD)

	Main role Mean (SD)	Assisting role Mean (SD)	Traditional belief about gender role Mean (SD)
<4,000	3.69 (1.15)	3.61 (1.32)	3.45 (1.45)
4,000 – 9,999	3.53 (.97)	3.17 (1.18)	3.05 (1.32)
10,000 – 14,999	3.56 (1.01)	3.22 (1.26)	3.05 (1.33)
15,000 – 19,999	3.42 (1.02)	3.16 (1.22)	3.01 (1.25)
20,000 – 29,999	3.42 (.95)	3.18 (1.17)	2.97 (1.24)
30,000 – 49,999	3.46 (.93)	3.04 (1.12)	2.88 (1.22)
50,000 – 79,999	3.39 (.95)	2.92 (1.12)	2.74 (1.16)
>80,000	3.38 (.97)	2.84 (1.10)	2.79 (1.18)
<i>F</i>	5.48***	20.18***	16.56***

*** $p < .001$.

Table 7 presents the mean scores for the three measures in different family income groups. For the main role in parenting, there was an overall reduced mean along with greater earning capacity of a family. The mean difference between groups is statistically significant ($F = 5.48$, $p = .000$, $\eta^2 = .006$). Post hoc tests indicated that the five higher-income groups (i.e., 15,000 – 19,999 and above) did not differ in terms of taking the major responsibility of child rearing, but they reported significant lower scores than the rest three groups did (10,000 – 14,999 and below). For performing assisting role, diminishing mean score was also found between groups with the household monthly income increased ($F = 20.18$, $p = .000$, $\eta^2 =$

.025). Post hoc comparison tests showed that parents from the highest income groups, i.e., groups 7 (50,000 – 79,999) and 8 (>80,000), reported significant lower scores in performing assisting role while the lowest income group, group 1 (<4,000), reported the highest. Similarly, as to the traditional belief ($F = 15.42$, $p = .000$, $\eta^2 = .019$), parents from group 1 were more likely to hold the traditional gender ideology, whereas parents from group 7 and 8 were less conservative on this matter. These findings basically supported Hypotheses 4a to 4c.

DISCUSSION

The purpose of the present study was to explore whether background socio-demographic factors are related to domestic division of labor in childcare in the context of Hong Kong. The first set of hypothesis (1a, 1b and 1c) were confirmed by the results shown in Table 2 that there was a gendered, unequal share of childcare among Hong Kong parents. Consistent with the majority of existing studies conducted elsewhere [10-12, 14, 33], Hong Kong mothers still assumed the main responsibility of childcare while fathers assumed the assisting role. We should also emphasize that the effect size for involving as main caregivers was medium ($\eta^2 = .04$), indicating a modest effect of gender on how childcare was divided between parents in practice. Meanwhile, results also showed that men were more likely to persist in believing the traditional gender concept “men are breadwinners and women are homemakers”, although the effect size was very small. The present findings are generally consistent with previous studies [35] that a more egalitarian gender attitude could not always be fully translated into a reshuffle of family roles in practice. This gendered phenomenon may have its root in Chinese cultural values. Chinese society has long held a cultural belief of gender differentiation in parenting, in which paternal role is to engage with market work while maternal role is to meet basic needs of children [32].

It is demonstrated by our findings that, in general, parents’ educational levels, family income and intensity of market work all negatively correlated to undertaking the main role in child rearing labor (although in some cases the effect size is very small), which supported hypotheses 2a, 2d, 3a and 4a. Results also suggested a negative association between these variables and taking an assisting role in parenting, which in general supported hypotheses 2b, 2e, 3b and 4b. The two results combined imply that higher educational and income level, and intensifier market work may suggest less engagement in parenting. It contradicts the findings in several existing literature [9, 27] in which they argued the opposite was true.

One possible explanation for this can be drawn from a rational economic perspective – time availability [36, 37]. Researchers argued that allocation of domestic tasks depended on the time availability of partners. This theorization, among others such as “doing gender” perspective [38] and relative resource perspective [39], may entail stronger explanatory power to the society of Hong Kong, due to the stressful living in the metropolis of Hong Kong with a high cost of living. Reports and studies [40, 41] have confirmed the situation of long working hours in Hong Kong. For example, The Swiss Investment Bank (UBS): Price and earning report (2015) [41] shows that Hong Kong people work for an average of more than 50 weekly working hours and 2,606 working hours per year, ranking the highest out of 71 cities across the world. It is likely that parents with higher educational level, greater earning

capacity and higher intensity of workforce participation may all inform more amount of time devoted to market work and therefore less free time available for performing childcare duties. In contrast, parents with less breadwinning stress or capability are more able to transfer their time into childcare.

This study also provides some empirical evidence that overall parents with better education, greater earning capacity and/or more commitment to market work tended to be more open-minded and hold a progressive gender attitude. In contrast, less education, less earning power and more free time lead to a more conservative attitude and conformity to the traditional gender norms. Therefore, hypotheses 2c, 2f, 3c, 3f, 4c were confirmed. The results are largely in tune with the positive association found between an equal gender attitude and multiple social variables such as education and income in other cultures [42, 43]. Given the observed positive association, our findings demonstrate that education and work can function as a vehicle to change one's gender attitudes and encourage gender equality in childcare participation.

While the findings are interesting and pioneer in nature, there are several limitations of the study. First, only five items were used to assess three aspects of family division of labor. Obviously, it would be helpful to use more items to assess these dimensions to make the measures more reliable. Second, the findings are based on self-report measures. It would be helpful to understand the actual behavior of oneself and one's spouse. Finally, as the data collected are cross-sectional in nature, it would be theoretically interesting to look at the impact of these socio-demographic factors over time. Despite these limitations, the present findings shed light on family division of labor in a Chinese context and the related socio-demographic correlates.

ABSTRACT

In this chapter we examine parental beliefs of 5,749 Chinese parents based on an indigenous scale developed in the Chinese context. Results showed that the scale and the subscales were internally consistent. Findings based on frequency analyses revealed that Chinese parents generally held positive beliefs about their roles and responsibilities in parenting. However, Chinese parents showed more conservative attitudes in educating children on sexuality issues. Some parents also did not realize the necessity of learning about parenting, implying that they may be ill-prepared for parenting. Further analyses revealed that mothers possessed stronger parental beliefs than fathers did. Parents with lower educational levels tended to be more conservative in parental beliefs. Family income and employment status were also identified to be predictors of parental beliefs. In general, parents with lower family income or being unemployed tended to hold stronger traditional beliefs about roles and responsibilities in parenting than did high-income or employed parents. The research findings underscore the importance of understanding parental beliefs in Chinese societies.

INTRODUCTION

Parental beliefs refer to parents' knowledge, attitudes, ideas, and concepts in parenting that are accepted to be correct which guide their parenting behavior [1, 2]. Parental beliefs provide parents with cognitive frameworks which they can follow to set parenting goals, identify children's demands, use parenting strategies, and lay the base of parenting practices [1, 3]. Previous research has demonstrated the positive effect of parental beliefs on child development, especially on children's academic performance and persistence [4].

Most research on parenting was conducted in the West or relied on frameworks developed in Western contexts. For example, parenting styles identified by Baumrind, including authoritarian, authoritative, permissive, traditional and rejecting-neglecting parenting [5], have been widely adopted as the theoretical framework of research on parenting. However, researchers trying to relate these styles in non-Western cultures often encounter difficulties when using this framework to interpret indigenous phenomena [6]. Wang and Chang [7] suggested that Western concepts and frameworks can hardly capture the essence of parenting in non-Western cultures. The reasons are twofold. Primarily, some concepts developed in Western cultures could be unidentified, vague or even misleading in other cultures [8]. Secondly, some indigenous phenomena in parenting practices, such as "training" (Jiao Xun) and "to love and to govern" (Guan) in Chinese culture, can be largely overlooked [8, 9]. This echoes LeVine's model of parenting, which identifies universal as well as cultural aspects of socialization goals of families [10]. As the majority of the existing scales measuring parenting were developed in Western cultures and in English, researchers have been calling for the development of indigenous scales that fit specific cultural contexts [11, 12].

Different from parenting in Western cultures, parenting in Chinese societies is strongly guided by Chinese philosophies such as Confucianism, Taoism, and Buddhism. Shek and Sun [12] identified some characteristics of Chinese parenting, including strict parental control, little personal space for children, different gender role expectation, and strong emphases on harmony, obligations, filial piety, and continuity of the family name. As for parenting in contemporary Chinese societies, Shek and Sun [12] also noted the changing nature of parenting in the Chinese contexts over time. For example, changes in the gender parental role expectation have been observed. Traditionally, Chinese fathers were considered "the masters of the family" who set strict regulations on children's behavior, while mothers were normally regarded as the "obedient one" taking care of the family and maintaining the harmony. However, mothers in contemporary China seem to be more involved in the socialization process and stricter than fathers do. Although researchers have been gradually aware of the importance of developing culturally sensitive instruments, many of them still rely on concepts and measures derived from the Western contexts [13]. Hence, there is a need to further examine parental beliefs in the Chinese context using indigenous scales.

Previous research has also highlighted the role of parental background socio-demographic characteristics in shaping parental beliefs. For example, as discussed earlier, gender differences between fathers and mothers have been observed. The role expectation of "strict father and kind mother" rooted in traditional Chinese culture may modify fathers' and mothers' parental beliefs [12]. Educational level has been considered another influential factor affecting parental beliefs. It is suggested that well-educated parents may be more

equipped with knowledge and skills in parenting, have a strong level of efficacy, and be less conservative in parenting. They may also hold more liberal attitudes toward human behavior, such as emphasizing gender equality and fair share in family responsibilities. Besides, family economic status is also believed to influence parental beliefs. Leung and Shek [14] pointed out that the primary mission of economically disadvantaged families is to get their children out of the poverty trajectory and to step into a more economically successful future. On the other hand, families with a higher economic status possess more educational resources, which may exert an impact on their parental beliefs. In the present study, gender, educational level, employment status, and family income were included as important parental socio-demographic characteristics. As few studies have examined beliefs about parental responsibilities in Chinese parents and the related correlates, this study attempted to examine the related normative profiles and the demographic correlates.

OUR STUDY

A total of 5,749 questionnaires were collected. After removing 42 invalid cases, 5,707 valid responses were used for analyses. Among them, 31% were fathers ($N = 1,770$) and 65% were mothers ($N = 3,710$). The age of the respondents ranged from 21 to 97 years old (mean = 52.3 years, $SD = 13.67$). Nearly half of the respondents (48.5%) reported having two children, 30.6% had one child, and 14.3% had three children. As to the educational level, 14.2% of the respondents attained primary school education or below, 17.1% completed lower secondary education, 31.1% finished secondary school, 6.7% attained matriculation education, 24.2% completed university or higher education, and 4.7% finished graduate school or above. Regarding employment status, 45.7% of the respondents were full-time employees, 10.6% worked part-time, 17% were homemaker, 20.9% were retired, and 1.3% were unemployed. As to the monthly family income, 21% of the participants reported a family income lower than HK\$14,999, 46% were between HK\$15,000 and HK\$49,999, 27% of the respondents had a family income higher than HK\$50,000.

Instruments

The Parental Roles and Responsibilities – Chinese Parental Beliefs Scale was administered in the present study. The initial scale contained 42 items. Participants were asked to indicate the degree of agreement with statements on parents' beliefs about their parental roles and responsibility on a five-point Likert scale (1 = strongly disagree; 5 = strongly agree). In the study of Lam, To and Kwong [13], the factorial validity of the questionnaire was examined by exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). The working sample was randomly split into two subsets. EFA was performed on one subset ($N = 2,925$), which resulted in a five-factor solution. Next, CFA was conducted on the second subset ($N = 2,596$). The results showed an acceptable goodness-of-fit indices of the tested model. Details of the development of the instrument, and the findings of EFA and CFA were reported in Lam, To and Kwong's work [13]. The final solution constituted of 23 items, which were categorized under five factors (i.e., subscales): parental

love and nurturing (7 items), parenthood as a normative life stage (4 items), readiness to relax and restrict parental control (4 items), parental guidance of the young (4 items), and fulfillment of children's needs (4 items).

Data Analyses

Descriptive statistics were used to generate percentage findings. A one-way analysis of variance (ANOVA) was used to investigate the relationships between parental beliefs (and the five factors) and the background socio-demographic characteristics, including gender, educational level, employment status, and family income. All analyses were performed using SPSS (Version 25.0).

FINDINGS

The scale showed good reliability ($\alpha = .80$). As shown in Table 1, the five subscales also demonstrated acceptable reliability ($\alpha s > .60$). The average inter-item correlation of the entire sample yielded a value of 0.23. The inter-item correlations among the five factors showed a relatively high inter-item correlation of each factor, ranging from .30 to .48 (see Table 1). Ferketich [15] suggested that for scales containing 10 or more items and with an alpha of .71, an average inter-item correlation of 0.2 is acceptable. These findings support the internal consistency of the scale. Cronbach's alpha, mean inter-item correlations, mean, standard deviation and correlation coefficients amongst the five subscales and the whole scale are shown in Table 1.

Table 1. Cronbach's alpha, mean inter-item correlations, mean, standard deviation and correlation coefficients amongst the five subscales and the whole scale

Subscales	Cronbach's alpha	Mean inter-item correlations	Mean (SD)	Subscales				
				1	2	3	4	5
Parental love and nurturing (7 items)	0.866	0.489	4.28 (0.59)	—	—	—	—	—
Parenthood as a normative life stage (4 items)	0.599	0.375	3.02 (0.87)	.039	—	—	—	—
Readiness to relax and restrict parental control (4 items)	0.709	0.304	3.87 (0.68)	.392	.227	—	—	—
Parental guidance of the young (4 items)	0.739	0.437	4.40 (0.58)	.544	.138	.222	—	—
Fulfillment of children's needs (4 items)	0.749	0.427	3.62 (0.78)	.417	.394	.160	.453	—
38-item whole scale	0.847	0.223	3.90 (0.46)	.755	.556	.585	.674	.736

Note. N = 5,707. All correlation coefficients are statistically significant at $p < .01$ (two-tailed).

Findings Based On Frequency Data

The details of the descriptive statistics and frequency data are illustrated in Table 2.

Parental Love and Nurturing

Most respondents showed a positive attitude in this domain ($M = 4.28$, $SD = .59$). For example, 87.98% agreed that parents should always pay close attention to their children's emotions. Similarly, almost 90% of the respondents agreed that parents should spare time to accompany their children as far as possible. However, around 6% of the respondents disagreed with the statement "parents have to teach their children knowledge about sex" ($M = 4.03$).

Parenthood as a Normative Life Stage

Respondents presented a neutral attitude of their perception of parenthood as a normative life stage ($M = 3.02$, $SD = .87$). The ratings ranged between 2.56 and 3.65. For example, 25.65% agreed that parenthood is developed naturally that there is no need to learn. If the number of neutral responses was taken into account, roughly half of the respondents did not feel the necessity to learn how to parent. Only 20.68% agreed that fostering children can allow the parents to be looked after when getting old.

Readiness to Relax and Restrict Parental Control

Participants showed a moderately positive attitude towards the four statements in this domain ($M = 3.87$, $SD = .68$). The ratings ranged between 3.21 and 4.27. The majority of respondents agreed that parents should respect the wishes of their children (87.10%) and not to impose their wishes on their children (72.48%). However, the statement "parents have to accept their children's sexual orientation, no matter it is homosexual or heterosexual" yielded a relatively low rating ($M = 3.21$). Almost one-third of the respondents disagreed with this statement.

Parental Guidance of the Young

Most respondents presented a clear and positive perception of their roles and responsibilities in providing guidance of the youth ($M = 4.40$, $SD = .58$). Among the four items, the lowest mean score was 4.21 and the highest was 4.57. For example, 91.44% of respondents agreed that when children do not meet the requirements, parents ought to provide appropriate guidance. In particular, around 93% of the respondents agreed that parents are responsible for preventing their children from getting into bad company.

Fulfillment of Children's Needs

The respondents reported a moderately positive attitude in this domain ($M = 3.62$, $SD = .78$, range from 3.06 to 3.87). The majority of respondents would try to meet their children's needs but in a reasonable manner. For example, 65% agreed that parents are responsible to provide financial support for their children to complete university education. Besides, although 65.6% agreed that if financially possible, parents should provide the best resources for their children, only 31.4% agreed that parents should meet the needs of their children as far as possible.

	Mean (SD)	1	2	3	4	5	Negative responses options (1-2)	Positive responses options (4-5)
		Strongly disagree	Disagree	Neutral	Agree	Strongly agree		
11 Parents have to keep the values of their own	3.65 (0.99)	188 (3.34%)	365 (6.49%)	1855 (33%)	2019 (35.92%)	1194 (21.24%)	553 (9.84%)	3213 (57.16%)
Subscale 3 Readiness to relax and restrict parental control								
12 Children's future development cannot be controlled by their parents	4.01 (1.01)	145 (2.58%)	262 (4.65%)	1168 (20.75%)	1872 (33.26%)	2182 (38.76%)	407 (7.23%)	4054 (72.02%)
13 Parents should respect the wishes of their children	4.27 (0.72)	17 (0.3%)	50 (0.89%)	660 (11.71%)	2551 (45.26%)	2358 (41.84%)	67 (1.19%)	4909 (87.1%)
14 Parents have to accept their children's sexual orientation, no matter it is homosexual or heterosexual	3.21 (1.31)	828 (14.74%)	753 (13.4%)	1578 (28.09%)	1329 (23.66%)	1130 (20.11%)	1581 (28.14%)	2459 (43.77%)
15 Parents should not impose their wishes on their children	4 (0.92)	89 (1.58%)	191 (3.4%)	1267 (22.54%)	2186 (38.89%)	1888 (33.59%)	280 (4.98%)	4074 (72.48%)
Subscale 4 Parental guidance of the young								
16 Parents' responsibility is to educate (to teach and to nurture) their children; to teach is to discipline, to nurture is to provide them needs such as food and clothing	4.21 (0.95)	122 (2.17%)	195 (3.46%)	768 (13.63%)	1865 (33.11%)	2683 (47.63%)	317 (5.63%)	4548 (80.74%)
17 Parents are responsible for preventing their children from getting into bad company	4.57 (0.67)	13 (0.23%)	49 (0.87%)	335 (5.94%)	1565 (27.74%)	3680 (65.23%)	62 (1.1%)	5245 (92.96%)
18 When children do not meet the requirements, parents ought to provide appropriate guidance	4.48 (0.68)	11 (0.2%)	29 (0.52%)	442 (7.85%)	1940 (34.46%)	3207 (56.97%)	40 (0.71%)	5147 (91.44%)
19 If circumstances allow, parents have to provide resources and opportunities so as to lay a good foundation for their children	4.35 (0.76)	30 (0.53%)	73 (1.29%)	609 (10.8%)	2114 (37.48%)	2815 (49.9%)	103 (1.83%)	4929 (87.38%)

Table 2. (Continued)

	Mean (SD)	1	2	3	4	5	Negative responses options (1-2)	Positive responses options (4-5)
		Strongly disagree	Disagree	Neutral	Agree	Strongly agree		
Subscale 5 Fulfillment of children's needs								
20 Parents should assist their children in preventing them from running into obstacles on important matters	3.68 (1.03)	161 (2.86%)	496 (8.81%)	1681 (29.85%)	1924 (34.16%)	1370 (24.33%)	657(11.67%)	3294(58.49%)
21 Parents are responsible to provide financial support for their children to complete university education	3.86 (1.03)	163 (2.89%)	319 (5.66%)	1485 (26.34%)	1861 (33.01%)	1810 (32.1%)	482(8.55%)	3671 (65.11%)

Relations between Parental Beliefs and Background Socio-Demographic Characteristics

The relationships between omnibus parental beliefs scale (including the five subscales) and parent's gender, educational level, employment status, and family income were examined.

Parental Gender

In general, mothers' scores on parental beliefs about parental roles and responsibilities ($M = 3.91$) were significantly higher than fathers' scores ($M = 3.86$, $F(1,5450) = 9.62$, $p < .01$). Compared to fathers, mothers tended to hold a stronger belief about loving and nurturing children, parenthood as a normative life stage and readiness to relax and restrict parental control. As to parental guidance of the young, no significant difference between fathers and mothers was observed. Different from other domains, fathers presented a stronger belief in responsibility in fulfilling children's needs than mothers did. Details of the means and the ANOVA results are shown in Table 3.

Table 3. Mean and ANOVA results: Parental beliefs and gender

Scale	ANOVA	Mean	
		Father	Mother
Whole scale	$F(1,5450) = 9.62$, $p = .002$	3.86	3.91
Factor 1	$F(1,5345) = 35.85$, $p < .001$	4.21	4.32
Factor 2	$F(1,5353) = 4.92$, $p = .027$	2.97	3.02
Factor 3	$F(1,5358) = 24.31$, $p < .001$	3.81	3.90
Factor 4	$F(1,5376) = 1.2$, ns	4.41	4.39
Factor 5	$F(1,5367) = 7.26$, $p = .007$	3.65	3.59

Note. Factor 1: Parental love and nurturing; Factor 2: Parenthood as a normative life stage; Factor 3: Readiness to relax and restrict parental control; Factor 4: Parental guidance of the young; Factor 5: Fulfillment of children's needs.

Educational Levels

Parents with higher educational level tended to report a lower level of parental belief about their parental roles and responsibilities than parents with a lower educational level ($F(5,5556) = 17.05$, $p < .001$). The results of post-hoc analyses indicated that parents with primary education or less held significantly stronger parental beliefs of their responsibilities than did parents with other educational levels. As to the subscales, similar patterns were found in loving and nurturing children, parenthood as a normative life stage and fulfillment of children's needs. No significant difference was found amongst parents with different educational levels regarding their beliefs in guidance of the young. Interestingly, parents with a higher educational level tended to possess a stronger belief in the readiness to relax and restrict parental control more than parents with lower educational levels (see Table 4).

Employment Status

The results of ANOVA revealed that parental beliefs differed among parents with different employment status ($F(5,5520) = 28.08$, $p < .001$). Generally speaking, parents who were employed, including full-time and part-time workers, tended to hold a weaker traditional parental belief than parents who were retired or social security recipients. Employment status was also significantly linked to parental beliefs in all of the five subscales (see Table 5).

Table 4. ANOVA results: Parental beliefs and respondent's educational levels

Scale	ANOVA	Mean					
		Primary or below	Lower secondary(a)	Completed secondary school(b)	Matriculate(c)	University/ Higher Education(d)	Graduate school or above(e)

Factor 5	$F(5,5473) = 27.5, p < .001$	0.88abcde	0.83	0.76	0.78	0.69	0.68

Note. Factor 1: Parental love and nurturing; Factor 2: Parenthood as a normative life stage; Factor 3: Readiness to relax and restrict parental control; Factor 4: Parental guidance of the young;

Factor 5: Fulfillment of children's needs. ns: not significant. abcde: Significant results of post-hoc comparison, $p < .05$.

Table 5. ANOVA results: Parental beliefs and respondent's employment status

Scale	ANOVA	Mean					
		Work full time	Work part time(a)	Full time homemaker(b)	Unemployed or between jobs(c)	Retired(d)	Social security recipient(e)
Whole scale	F(5,5520) = 28.08, p < .001	3.84bde	3.84	3.90	3.92	4.02	4.02
Factor 1	F(5,5415) = 11.78, p < .001	4.28bd	4.27	4.39	4.32	4.19	4.27
Factor 2	F(5,5426) = 95.56, p < .001	2.87cde	2.92	2.88	3.08	3.45	3.55
Factor 3	F(5,5433) = 5.98, p < .001	3.85d	3.80	3.88	3.97	3.95	3.74
Factor 4	F(5,5449) = 12.5, p < .001	4.36bd	4.33	4.42	4.38	4.51	4.44
Factor 5	F(5,5439) = 37.08, p < .001	3.53de	3.55	3.54	3.59	3.87	3.92

Note. Factor 1: Parental love and nurturing; Factor 2: Parenthood as a normative life stage; Factor 3: Readiness to relax and restrict parental control; Factor 4: Parental guidance of the young;

Factor 5: Fulfillment of children's needs. abcde: Significant results of post-hoc comparison, $p < .05$.

The results and patterns found in parenthood as a normative life stage and fulfillment of children’s needs were similar to the findings derived from the analysis based on the whole scale. As to the domain on parental love and nurturing, full-time homemakers displayed the highest level of parental belief. Regarding the readiness to relax and restrict parental control, parents who were unemployed and retired showed a stronger belief than did parents with other types of employment status. As to parental guidance of the young, the biggest difference was found between parents who were full time employed ($M_s < 4.36$) and retired ($M = 4.51$). Details of the means and the ANOVA results are shown in Table 5.

Family Income

Generally speaking, parents with a relatively lower family income (i.e., lower than HK\$14,999) tended to present a stronger parental belief about their roles and responsibilities than did parents with relatively higher family income (i.e. between HK\$15,000 and HK\$49,999, and above HK\$50,000), $F(2,5304) = 24.36, p < .001$. Post-hoc analyses revealed a significant difference between parents having a family income below HK\$14,999 and parents in the other two groups. As to parental guidance of the young, no significant difference was observed. However, high-income parents reported stronger beliefs about their responsibilities in love and nurturing. Details of the means and the ANOVA results are shown in Table 6.

Table 6. ANOVA results: Parental beliefs and respondent’s family income

		Mean		
		Below HK\$ 14,999	HK\$15,000 – HK\$49,999(a)	Above HK\$50,000(b)
Whole scale	$F(2,5304) = 24.36, p < .001$	3.96ab	3.86	3.86
Factor 1	$F(2,5206) = 10.85, p < .001$	4.23b	4.26	4.33
Factor 2	$F(2,5220) = 142.61, p < .001$	3.32ab	2.97	2.78
Factor 3	$F(2,5228) = 5.88, p = .003$	3.87	3.84	3.91
Factor 4	$F(2,5236) = 2.25, ns$	4.41	4.37	4.40
Factor 5	$F(2,5227) = 42.31, p < .001$	3.77ab	3.58	3.50

Note. Factor 1: Parental love and nurturing; Factor 2: Parenthood as a normative life stage; Factor 3: Readiness to relax and restrict parental control; Factor 4: Parental guidance of the young; Factor 5: Fulfillment of children’s needs. ns: not significant. ab: Significant results of post-hoc comparison, $p < .05$.

DISCUSSION

Based on the data collected from 5,707 parents in Hong Kong, the present study provides pioneer findings of Chinese parental beliefs about roles and responsibilities. Some unique features of the present study should be highlighted. First, this indigenous scale used in the present study is the first known scale developed using a “bottom-up” approach to explore parental beliefs in Hong Kong. As studies on parenting have recognized the tremendous influence of cultural context in shaping parents’ beliefs and behaviors [16], this culture sensitive measure of parental beliefs can help researchers pursue in-depth understanding of parental beliefs in Hong Kong, where the local culture is a mix of traditional Chinese and contemporary Western influence [13]. Second, the large sample used in the present study contributed to the robust findings. In particular, the sample presented a good mix of different

levels of socioeconomic status. Third, this study collected survey data from both fathers and mothers. This fills the research gap that studies on parenting in Chinese societies primarily focus on maternal parenting [17, 18]. Finally, the findings have theoretical and practical implications for parenting in the Chinese context.

The study examined the reliability and frequency percentage of Chinese Parental Beliefs Scale, and explored the relation between parental beliefs and their background socio-demographic characteristics. The findings showed that the scale and subscales possessed good internal consistency. Given that related psychosocial measures in different Chinese societies are rare, this measurement is shown to be a valid and useful tool measuring parental beliefs in the Chinese context.

The percentage findings showed that Hong Kong parents in general held positive beliefs about their roles and responsibilities in parenting. This is in line with Chinese culture which emphasizes parental responsibilities in raising, educating and guiding children to become respectable and functioning members of the family and the society. For example, in the family instruction of Master Yan (*The Yan Shi Jia Xun*), one of the most influential Family Instruction books, parental strictness, dignity, and parental love are emphasized, as these factors will lead the children to the feelings of respect, politeness, and filial piety [19]. This can be further explained by a Chinese saying, “It is the fault of the father if he only raises the child without teaching him” (*yang bu jiao, fu zhi guo*), which indicates strong parental responsibilities perceived by Chinese parents.

Although parents can be aware of their responsibilities in preparing their children to lead a worthy life and to become a good person [16], they seemed to be less affirmative about their role in providing knowledge and guidance of sex-related issues. For example, the results indicated that almost a quarter of respondents did not regard teaching children knowledge about sex as parents’ responsibilities. Similarly, more than half of the respondents did not agree that parents should accept children’s sexual orientation no matter homosexual or heterosexual. Previous studies on sex education in Chinese societies revealed that Chinese parents tend to be conservative about direct discussion of sex-related issues with their children or provide direct guidance to them [20, 21]. Leung and colleagues [22] reviewed sexuality education programs in both Western and non-Western contexts, noted that the perception of sex as a “taboo” is still deeply rooted in Chinese cultures, and even school sexuality programs were covered by conservative materials in mainland China. Besides, roughly half of the respondents did not realize the necessity of learning about parenting. This may imply a lack of awareness of the importance of parenting skills and strategies on child development among some parents in Hong Kong. This finding suggests that some parents are not well-prepared for parenting, which would lead to parenting and parent-child relationship problems. In traditional Chinese culture, people held the belief that “God will help feed all the children that one has faith to bear” (*tian sheng tian yang*). Hence, Chinese people do not hold a strong belief that parenting education is needed for being a parent.

The results also revealed how parental beliefs vary among parents with different background socio-demographic characteristics. First, gender difference was observed, showing that mothers held stronger parental beliefs than fathers did. The result is consistent with the gender expectations of Chinese society where men are often seen as breadwinner and women as housemakers. This finding also echoes some related empirical studies. For example, some cross-sectional and longitudinal studies have suggested that mothers scored higher on positive parenting qualities than fathers in Chinese societies [23, 24]. Shek and Sun

[12] pointed out that mothers were seen as more positive in parental control and parent-child relational measures, and are also more involved and stricter than fathers did in contemporary China.

Regarding the educational level, parents who had completed a relatively lower education level showed more conservative or collectivistic attitudes of parenting. The results also indicated that the retired or social security recipients tended to possess stronger parental beliefs than parents with other working status. Similarly, low-income parents seemed to hold stronger beliefs about parental responsibilities and roles than high-income parents. A possible explanation for these findings is that parents of low socioeconomic status may feel unable to fully meet their children's needs. Therefore, they may set a higher standard for themselves for being responsible parents. However, those with higher educational level tended to show a higher acceptance level for their children. They may also hold more liberal parenting beliefs.

Although the present findings are pioneer in nature, some limitations of the present study should be addressed. First, this culture sensitive scale was developed via a "bottom-up" approach based on interview data collected from 120 Hong Kong parents. Therefore, it is necessary to include other samples such as Chinese parents in Mainland and Macau. Second, existing scales can be used as validated external criterion measures to consolidate the validity of the scale. Third, as the sample was not randomly selected, obtaining a random sample of parents would be helpful to give a more representative picture of parental behavior in Hong Kong. Finally, besides sexuality, it would be illuminating to understand parental expectations of roles and responsibilities in different domains of child development, such as intellectual and interpersonal competence development.

ABSTRACT

Parenting in Hong Kong is shaped by traditional Chinese collectivistic values and contemporary Western individualistic influences. In this chapter, we focus on parenting phenomena in Hong Kong. While traditional Chinese parenting goals are still dominant, there are gradual changes in parenting in Hong Kong. The traditional pattern of “strict fathers, kind mothers” has changed to “kind fathers, strict mothers” and “detached fathers, involved mothers”. Consistent with the Western literature, parenting is related to different child developmental outcomes, although the influences of paternal and maternal parenting lead to different outcomes. Relative to families without risk, financially poor and non-intact families show poorer parenting quality. Parenting is also related to other family processes, including family functioning and dyadic family processes such as parent-child relational qualities. The unanswered questions and future research directions are also highlighted.

INTRODUCTION

Parenting research is dominated by Western studies. As such, whether Western findings are generalizable to non-Western societies and whether unique parenting phenomena exists in non-Western contexts are questions to be addressed. Against this background, there are two

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

reasons why researchers should understand parenting in Chinese societies. First, as roughly one-fifth of the world's population are Chinese, generalizability of Western parenting theories and research should be examined in Chinese people [1]. Second, parenting is strongly emphasized in traditional Chinese culture, as reflected by the existence of many Chinese family instruction books. Hence, it is theoretically and practically interesting to understand Chinese parenting [2]. For example, as shown in Table 1, traditional Chinese parenting literature emphasizes the importance of self-cultivation, particularly the development of virtues and character of children. Besides, parents should nurture frugality, simple life, as well as gratefulness to nature and other people in their children.

Furthermore, traditional Chinese parenting also emphasizes the role modeling of filial piety. Adults exercise a high level of filial piety to their parents; at the same time, they are the role models of their children. Moreover, one of the major goals of parenting is to maintain family harmony. These emphases are in sharp contrast to the focus of Western parenting literature which highlights the importance of well-being (such as happiness and life satisfaction), holistic development, individual rights, and personal autonomy in children.

Parenting research in Hong Kong is reviewed in current paper. Hong Kong can be regarded as a paradise for parenting research because roughly 92% of the population in Hong Kong are Chinese, where Chinese cultural values, such as filial piety and academic excellence, shape people's parenting practice. Besides, Hong Kong is a melting pot of Chinese and Western parenting beliefs and practice. This review focuses on the following issues: a) parenting phenomena in Hong Kong; b) parenting differences between fathers and mothers; c) parental influences on adolescent development; d) paternal versus maternal influence on adolescent development; e) parenting in high-risk families; f) parenting and other family processes; and g) limitations of the existing scientific literature and future research directions.

Table 1. Examples of traditional Chinese parenting instructions

《誠子書》——諸葛亮（三國時期） 『夫君子之行，靜以修身，儉以養德。非淡泊無以明志，非寧靜無以致遠。』 Jie Zi Shu (Admonition to My Son) -- Zhuge Liang (Three Kingdoms Period) “The practice of a cultivated man is to refine himself by quietude and develop virtue by frugality. Without detachment, there is no way to clarify the will; without serenity, there is no way to get far.” Xie, B.K. & Chen, Q.D. (2013). English Bus. Retrieved from: http://www.en84.com/dianji/wenji/201301/00011820.html 《朱子家訓》——朱柏廬（明末清初） 『黎明即起，灑掃庭除，要內外整潔；既昏便息，關鎖門戶，必親自檢點。一粥一飯，當思來處不易；半絲半縷，恒念物力維艱。宜未雨而綢繆，毋臨渴而掘井。自奉必須儉約，宴客切勿留連。器具質而潔，瓦缶勝金玉；飲食約而精，園蔬愈珍饈。勿營華屋，勿謀良田。三姑六婆，實淫盜之媒；婢美妾嬌，非閨房之福。童僕勿用俊美，妻妾切忌豔妝。祖宗雖遠，祭祀不可不誠；子孫雖愚，經書不可不讀。居身務期儉約；教子要有義方。莫貪意外之財，莫飲過量之酒。與肩挑貿易，毋佔便宜；見窮苦親鄰，須加溫恤。刻薄成家，理無久享；倫常乖舛，立見消亡。兄弟叔姪，須分多潤寡；長幼內外，宜法肅辭嚴。聽婦言，乖骨肉，豈是丈夫？重賞財，薄父母，不成人子。嫁女擇佳婿，毋索重聘；娶媳求淑女，勿計厚奩。見富貴而生諂容者，最可恥；遇貧窮而作驕態者，賤莫甚。居家戒爭訟，訟則終凶；處世戒多言，言多必失。勿恃勢力而凌逼孤寡；毋貪口腹而恣殺牲畜。乖僻自是，悔誤必多，類情自甘，家道難成。狎昵惡少，久必受其累；屈志老成，急則可相依。輕聽發言，安知非人之謬想？當忍耐三思；因事相爭，焉知非我之不是？須平心再想。施惠無念，受恩莫忘。凡事當留餘地，得意不宜再往。人有喜慶，不可生妒忌心；人有禍患，不可生喜幸心。善欲人見，不是真善；惡恐人知，便是大惡。見色而起淫心，報在妻女；匿怨而用暗箭，禍延子孫。家門和順，雖饗饕不繼，亦有餘歡；國課早完，即囊橐無餘，自得至樂，讀書志在聖賢，非徒科第；為官心存君國，豈計身家？守分安命，順時聽天。為人若此，庶乎近焉。』

Master Chu's Homilies for Families – Zhu Bolu (End of Ming Dynasty and Beginning of Qing Dynasty)

“Rise up by dawn's early light; clean up, put everything right; keep the home tidy and clean. Go to bed early at night; check that the doors are locked tight; sleep now secure and serene. The growing of rice and of grain Think on whenever you dine; remember how silk is obtained which keeps you warm and looks fine. In periods of drought wise birds mend their nest so when the clouds burst they snugly may rest; never be the fool who starts to dig a well in the ground when he wants a drink of water and water can't be found. Restrained and frugal be in all your private life; that party quickly flee with drinking and flirting rife. Oh better earthen mugs and plates in household neat and clean than vessels made of gold and jade and suited for the queen; eat good food from garden fresh downed with a cup of tea Shun exotic, unknown foods from far across the sea. Build not a house too pretentious and grand; never, no never take anyone's land. Matchmaker ladies who wander out and in don't mediate matches, they mediate sin; a beautiful and lusty young wife may complicate a family's life. A page-boy clever, quick and sharp you should never, never hire; of over made-up, dressed-up wife you certainly will tire. Memorial service for forebears you now and then should hold; to learn from them and show you care, their story should be told. Confucius' classic sayings all children should retain, specially when it's evident They do not have much brain. Honest and righteous be and committed to good deed; your children then will see example they should heed. You can only make a fortune by Striving, working hard; no money falls from out the sky on your own backyard. Only drink a small amount of good wine never let yourself across the sober line. Bargain you not with the traveller who vends; share of your wealth with your neighbors and friends. The man who gets rich through his lying and cheating, will find that his joy -- if any -- is fleeting. A person who commits incest Is foul knave whom all detest. When splitting the family fortune be fair so siblings and cousins will each get their share; domestic law rates everyone par no matter how haughty or humble you are. No worthy son his honor stains by giving any credence when wife, in pillow talk, complains about his antecedents. When selfish son for riches seeks neglecting aging parents then all should treat him as a freak, his actions an aberrance. A costly betrothal cannot ensure, that daughter's marriage will always endure. A nice woman with no dowry makes a good wife; a woman with large dowry may bring stress and strife. To fawn on the rich detracts from your fame and despising the poor redounds to your shame. Don't take into court your family disputes, unpleasant endings emerge from lawsuits; to comport yourself well in society restrain loose tongue's impropriety. Use not your bow and arrow to bully orphan and widow. Do not dumb animals slaughter at will your appetite greedy to over fulfil. Egocentric people grow, much regret and sorrow; lazy, slothful people sow, poverty tomorrow. He who with crooks his way does wend, into crime will surely drift; rely on honest upright friend, when from plight you need a lift. A remark that's made with seeming candor, could really be malicious slander; so carefully now think it through. And when with friend you've had a fight, consider this: perhaps he's right; it may be that fault is with you. In proclaiming your virtue go slow; and be mindful of mercy you owe. Leave room for retreat when trying new feat. You will try, try in vain to repeat windfall gain. Don't envy other's success; don't gloat o'er other's distress. To brag of the good you have done will never impress anyone. Personal scandals you try hard to hide, will soon be known far and wide. The husband who yields to his lustful desire. By letting his lewd fancies roam, thus forfeits his privilege to hope or aspire, to having a warm, happy home. A stab in the back of a man that you hate, will subject your sons to an even worse fate. The family that lives in love and peace, is garnering joys that never will cease even though your food may decrease. Paying tax early to the state, makes you feel contented and great even though your purse will deflate. Sages and men of good virtue inspire, true scholar's heart with a studious fire. If to high office you truly aspire, you must be loyal to king and empire. You are not far from being a good person, if you abide by the law, believe in destiny, following the trend of the time sand adapt to the changes of nature.”

《孝經》—— 儒家經典 (秦、漢時期)

『孝子之事親也，居則致其敬，養則致其樂，病則致其憂，喪則致其哀，祭則致其嚴。五者備矣，然後能事親。』

The Classic of Filial Piety – Confucianism classic (Qin Dynasty and Han Dynasty)

“The service which a filial son does to his parents is as follows: In his general conduct to them, he manifests the utmost reverence. In his nourishing of them, his endeavor is to give them the utmost pleasure. When they are ill, he feels the greatest anxiety. In mourning for them (dead), he exhibits every demonstration of grief. In sacrificing to them, he displays the utmost solemnity. When a son is complete in these five things, (he may be pronounced) able to serve his parents.” (p. 480)

Legge, J. (1879). *The Sacred Books Of China*. Oxford: The Clarendon Press.

《孟子》——孟子（戰國時期）

『公孫醜曰：「君子之不教子，何也？」』

孟子曰：「勢不行也。教者必以正；以正不行，繼之以怒；繼之以怒，則反夷矣。『夫子教我以正，夫子未出於正也。』則是父子相夷也。父子相夷，則惡矣。古者易子而教之。父子之間不責善。責善則離，離則不祥莫大焉。」

The Works of Mencius – Mencius (Warring States Period)

“Gong Sun Chou said, ‘Why is it that the superior man does not himself teach his son?’

Mencius replied, ‘The circumstances of the case forbid its being done. The teacher must inculcate what is correct. When he inculcates what is correct, and his lessons are not practised, he follows them up with being angry. When he follows them up with being angry, then, contrary to what should be, he is offended with his son. At the same time, the pupil says, ‘My master inculcates on me what is correct, and he himself does not proceed in a correct path.’ The result of this is, that father and son are offended with each other. When father and son come to be offended with each other, the case is evil. The ancients exchanged sons, and one taught the son of another. Between father and son, there should be no reproving admonitions to what is good. Such reproofs lead to alienation, and than alienation there is nothing more inauspicious.” (p. 308)

PARENTING PHENOMENA IN HONG KONG

Table 2. Frequency of responses to the items of the Chinese Paternal Control Scale (CPCS) and Chinese Maternal Control Scale (CMCS)

Item	Responses to the Chinese Paternal Control Scale (Grade 7 to Grade 9)	Responses to the Chinese Maternal Control Scale (Grade 7 to Grade 9)
1. My father/mother expects me to be mature (sheng xing).	Ranged from 86.4% to 91.0%	Ranged from 91.9% to 95.3%
2. My father/mother expects me to be obedient (“guai” and “ting hua”).	Ranged from 90.0 to 91.9%	Ranged from 94.1% to 96.0%
3. My father/mother expects me to have good virtues and behavior.	Ranged from 93.4 to 94.5%	Ranged from 94.9% to 96.9%
4. My father/mother expects me to have good behavior so that I will not bring dishonor to the family (“you ru jia sheng”).	Ranged from 51.1% to 52.0%	Ranged from 53.5% to 54.8%
5. My father/mother expects me to have good behavior so that he/she will not be criticized by others as having no family teaching (“wu jia jiao”).	Ranged from 47.6% to 58.6%	Ranged from 41.2% to 62.5%
6. My father/mother expects me to respect him/her.	Ranged from 73.0% to 75.5%	Ranged from 78.6% to 80.0%
7. My father/mother is very harsh in his/her discipline.	Ranged from 34.3% to 59.7%	Ranged from 40.6% to 47.1%
8. My father/mother always teaches me about the ways of dealing with one self and others.	Ranged from 72.8% to 74.4%	Ranged from 73.0% to 75.6%
9. When I do something wrong, my father/mother requires me to have self-reflection.	Ranged from 67.0% to 69.3%	Ranged from 74.7% to 75.3%
10. When I do something wrong, my father/mother teaches me (“jiao xun”).	Ranged from 58.5% to 59.8%	Ranged from 68.8% to 70.0%
11. When I don’t meet my father’s/mother’s expectation, he/she urges me (“du cu”) to work hard.	Ranged from 72.6% to 75.5%	Ranged from 83.0% to 85.3%
12. My father/mother expects me to interact with older people (“zhang bei”) with respect and courtesy.	Ranged from 92.1% to 94.2%	Ranged from 95.1% to 96.9%

Note: Cumulative percentage figure for each grade = sum of the percentage of responses to the “Agree” and “Strongly Agree” response options. Re-constructed from Shek (2008).

There are several unique parenting features in contemporary Hong Kong. First, Shek [3] found that traditional Chinese socialization goals, such as expectations about maturity, having good virtues and respecting old people, still occupied a strong role in Hong Kong (see Table 2). Second, contemporary Chinese parents emphasized on three socialization goals, which were academic excellence, “obeying” parental instructions and non-engagement of problem behavior [4]. Third, Hong Kong parents still strongly emphasized their children’s academic excellence and they tended to sacrifice their own interests to facilitate their children’s education [5]. Fourth, Chinese parents exercised high behavioral control in academic domain but not in peer domain [6]. Fifth, some of the traditional features of Chinese parenting have been weakened, such as decline in parental harshness, parental teaching (“jiao xun”), and avoidance of bringing dishonor to the family (Table 2). Sixth, Chinese parents typically exhibited high psychological control, although they also showed concerns about their children [7]. In Chan, Leung, Tsang, Lu, and Fok’s [8] study on parenting practice in Hong Kong, it was found that parental warmth has increased in the past 15 years.

Finally, Shek and Sun [2] pointed out that there were several worrying parenting phenomena in contemporary Hong Kong, including the lack of time to spend with children, drop in family solidarity, over-reliance on imported domestic helpers, and comparatively poorer parenting attributes as compared to those in other places. In addition, Shek [9] pointed out that the pragmatic emphases, such as the parenting beliefs of “not to lose at the starting line” and “academic excellence is the most important attribute of a good child”, are shaping parenting practice in contemporary Hong Kong.

PATERNAL PARENTING VERSUS MATERNAL PARENTING

Differences between fathers and mothers on different parenting measures have been reported. For example, Shek [10] found that fathers were seen as higher in restrictiveness but lower in concern as compared to mothers among high school students. Utilizing longitudinal data collected from adolescents, Shek [11] found that while fathers were seen as less responsive, demanding, concerning, communicative, and being liked by their children as compared to mothers, adolescents perceived paternal harshness to be higher than maternal harshness. In another three-year longitudinal study, Shek [12] found that paternal knowledge, expectation, monitoring, discipline, responsiveness, demandingness, parental control defined by indigenous Chinese concepts and dyadic relational qualities (mutual trust and communication) were poorer than those of mothers. However, maternal psychological control was higher than paternal psychological control [12]. In a recent 6-year longitudinal study [13], perceived maternal behavioral control, knowledge, expectations and monitoring were found to be more positive as compared to perceived paternal behavioral control, knowledge, expectation and monitoring. The study further showed that differential parenting persisted in the senior high school years. Such observation is important because “differences between maternal and paternal parenting styles have received less attention, particularly in the case of late adolescents” [14].

In another study conducted by Chan et al. [8], maternal warmth was higher than paternal warmth amongst children aged 9-14 years. However, compared with mothers, fathers showed lower dysfunctional parenting practice, behavioral control, psychological control and Chinese

parental control. Similar findings were reported in secondary school students [15]. Based on the responses of adolescent children, Leung and Shek [16] reported that fathers were less responsive, demanding, controlling and sacrificial for children's education than did the mothers, and the differences were triangulated by the findings based on the responses of both parents.

Interestingly, the available research showed that there was a shift in parenting attributes in contemporary fathers and mothers in Hong Kong. Traditional Chinese parenting was commonly conceived in terms of "strict fathers, kind mothers", where fathers were harsh while mothers were lenient. However, parenting research in Hong Kong suggested that Chinese parenting has been changed to "kind fathers, strict mothers" and "detached fathers, involved mothers", where mothers are relatively more demanding, controlling and have more monitoring about their children than fathers [12]. Besides, as compared to fathers, mothers are also more involved and show more affection in children's socialization process.

PARENTING INFLUENCES ON ADOLESCENT DEVELOPMENT

Consistent with the Western literature, cross-sectional studies suggested that parenting influences the development of children and adolescent in Hong Kong. Shek [17] found that the parental treatment styles were negatively related to high school students' psychological symptoms (anxiety, depression, somatic symptoms and general psychological symptoms) and positively related to their positive mental health (purpose in life and ego strength). Based on Chinese high school students, Shek [18] found that while global parenting style and specific parenting behavior were negatively related to general psychological symptoms and hopelessness, these parenting attributes were positively related to purpose in life, life satisfaction, self-esteem, academic achievement and school conduct. Parenting characteristics were also positively related to adolescent developmental outcomes in the general adolescent population [8] and high-risk families [19]. McBride and Chang [20] pointed out that while authoritative parenting style was related to autonomy, parenting style was not related to school achievement. Parenting emphasizing autonomy in children also facilitated prosocial behavior [21].

There are not many longitudinal studies examining the impact of parenting on child developmental outcomes in Hong Kong. Shek [22] showed that adolescents who perceived their parents as concerning, restrictive, responsive or demanding had better positive mental health, including purpose in life and life satisfaction. Similarly, those who had a more positive perception of parenting attributes displayed fewer psychological symptoms. In a 6-year longitudinal study in the Project P.A.T.H.S. [13], it was found that higher parental control and better parent-child relationship were related to higher life satisfaction, purpose in life and psychosocial competence (such as emotional competence and resilience), and lower adolescent risk behavior, including hopelessness, Internet addiction, delinquency, consumption of pornography, self-harm and suicidal behavior. On the other hand, psychological control was negatively related to psychological well-being but positively related to risk behavior [13]. Similar findings were observed in high-risk families. Based on two waves of data collected from poor families, Shek [23] showed that more positive

parenting attributes were related to better subjective well-being and lower psychological morbidity and hopelessness.

PATERNAL INFLUENCE VERSUS MATERNAL INFLUENCE ON CHILD DEVELOPMENT

Although there are studies examining the influence of parenting on child development, only few studies have examined the relative contribution of fathers and mothers to different aspects of adolescent development. Primarily, there are studies showing the relatively stronger influence of paternal parenting relative to maternal parenting. Based on the responses of high school students to questionnaire measures over two years, Shek [22] showed that parenting styles and parenting behavior were related to psychological symptoms and positive mental health concurrently and over time, and the relationships were reciprocal in nature. Besides, paternal parenting showed stronger influence on adolescent development. Based on the same study, Shek [24] integrated questionnaire (global and specific parenting) and interview measures (feelings about parenting, parent-adolescent communication) to form new measures of “paternal parenting qualities” and “maternal parenting qualities”. While maternal parenting qualities did not predict changes in the adolescent developmental outcomes, paternal parenting qualities predicted changes in psychological morbidity indexed by hopelessness, general psychological symptoms, and eudaimonic mental health indexed by life meaning, life satisfaction, and self-esteem.

There are also studies showing that paternal parenting and maternal parenting are both related to different child outcomes, but their effects may differ across genders of adolescents. Shek [23] examined the influence of paternal and maternal parenthood qualities on development of adolescents from poor families. At a particular time, different parenting factors were correlated with adolescent developmental outcome measured using cross-sectional data. However, there was no strong support for the hypothesis that adolescent developmental outcomes were influenced by parenting over time. Nevertheless, while paternal parenting influenced mental health and problem behavior in adolescent boys, but not in adolescent girls, maternal parenting influenced mental health and problem behavior in adolescent girls, but not in adolescent boys [23]. Based on poor Chinese families, Leung and Shek [25] found that while the expectation of fathers on the future of their children predicted perceived maternal control and adolescent development, maternal control mediated the influence of parental beliefs on adolescent psychosocial competences. Ren, Zhang, Yang, and Song [26] also found that supportive parenting and the role of fathers were important in shaping mathematics competence and behavioral problem in young children.

PARENTING QUALITIES IN HIGH-RISK FAMILIES

Compared with non-vulnerable families, parenting in vulnerable families are relatively poorer. In several cross-sectional studies, compared to intact families (i.e., parents were in their first marriage), parents in non-intact families (i.e., divorced, separated, remarried and other forms of marriages of the parents) showed less concern, responsiveness, knowledge and

monitoring to their children, but more and harsher punishment [27]. Similar results were reported in the Chan et al. [8] study on parenting in Hong Kong, which indicated that parenting attributes were more positive in intact families than in non-intact families.

The relative poorer parenting attributes in non-intact families were also reported in longitudinal studies. In a 3-year longitudinal study, we found that perceived parental behavioral control, responsiveness, demandingness, and perceived parenting based on indigenous Chinese concepts were comparatively poorer in adolescents from families experiencing parental marital disruption as compared to those from families with no parental marital disruption [28]. In another longitudinal study utilizing six waves of data, adolescents in non-intact families had a less favorable perception of paternal behavior control, including parental knowledge, expectation and monitoring. Similar findings were obtained for maternal behavioral control, maternal knowledge, maternal expectations and monitoring and maternal psychological control in each wave of data [13].

Economic disadvantage is also a risk factor in parenting. In several cross-sectional studies, adolescents from poor families perceived parenting to be less favorable as compared to adolescents from non-poor families [29]. Similar findings were revealed in a three-year longitudinal study, which showed that adolescents from poor families perceived parental behavioral control (indexed by Western measures of parental knowledge, expectation, monitoring, discipline, demandingness and indigenous Chinese measure of parental control) to be less favorable than did adolescents from non-poor families. In contrast, adolescents with family economic disadvantage perceived psychological control to be stronger than did adolescents without family economic disadvantage [30]. In the 6-wave longitudinal study in the Project P.A.T.H.S., adolescents from poor families perceived parental behavioral control and parent-child relational quality to be lower as compared to adolescents from non-poor families at different time points [13]. In addition, relative to adolescents from non-poor families, adolescents from poor families perceived parental psychological control to be higher.

PARENTING AND OTHER FAMILY PROCESSES

Research showed that different types and dimensions of parenting were inter-related. With reference to the different components of behavioral control (expectations, discipline, monitoring and knowledge), cross-sectional and longitudinal findings suggested that they were generally related in a positive manner [12]. For example, parents who have higher monitoring of their children would have more knowledge about their children. Besides, parental behavioral control (such as monitoring the whereabouts of children) was negatively associated with psychological control (such as withdrawal of love and inducing guilt in children). Furthermore, Shek [31] showed that different dimensions of global parental treatment styles (concern and harshness) and specific parenting behavior (responsiveness and demandingness) were inter-related. In addition, global parenting was associated with specific parenting. While parental responsiveness was positively related to different measures of parental behavioral control, it was negatively related to parental psychological control [12].

Furthermore, parenting quality is related to other dyadic family processes. Shek [32] showed that higher parental behavioral control and lower parental psychological control were

related to higher perceived parental trust of children and children's trust of their parents. Based on two waves of longitudinal data, Shek [33] showed that parenting attributes were related to parent-adolescent conflict at the same time and over time. Besides, findings showed that while parenting influenced parent-adolescent conflict, parent-adolescent conflict also influenced parenting.

Finally, parenting as a dyadic family process is related to systemic family functioning. Shek [34] examined the relationships between dyadic family relationships, which included measures based on parents and adolescent children reports of parenting style and parent-adolescent conflict and systemic family functioning measures. He found that family functioning based on the perspectives of parents and children was related to dyadic family processes, including parenting. Relative to perceived mother-child relationship and marital quality reported by mothers, perceived father-child relationship and marital quality showed stronger influence on systemic family functioning over time. In the six-wave longitudinal study in the Project P.A.T.H.S., while parental behavioral control and parent-child relationship were positively related to family functioning, parental psychological control was negatively related to systemic family functioning [13].

There are also findings showing that parenting mediates the impacts of parental behavior on child developmental outcomes. Based on the data collected from single-parent families, Leung and Shek [35] found that responsiveness and demandingness of mothers influenced filial piety which in turn affected positive development in adolescents. Filial piety was also identified as a moderator of the influence of maternal control on mother-adolescent relationship [36].

UNANSWERED QUESTIONS AND FUTURE RESEARCH DIRECTIONS

Based on 90 studies captured by PsycINFO, Fok and Shek [37] highlighted three conceptual limitations of parenting research in Hong Kong. These included paucity of parenting research utilizing indigenous Chinese parenting concepts, inadequate conceptual models examining causes, correlates and consequences of parenting, and failures to consider alternative explanations for the findings for those studies examining relationship between parenting and other constructs. In another paper [38], they further argued that there were eight methodological limitations of parenting research in Hong Kong, including predominant use of translated and non-validated Western measures, lack of longitudinal research studies, infrequent employment of multiple indicators to assess different parenting constructs, over-reliance on convenience sampling, insufficient use of hierarchical linear modeling looking at individual and cluster effects, paucity of qualitative studies of parenting.

With reference to the conceptual and methodological limitations of the field, there are several future research directions. First, with five thousand years' history, research on traditional Chinese parenting is grossly inadequate. It would be helpful to understand indigenous forms of parenting [38]. Besides, it would be helpful to understand more on how traditional parenting is related to modern parenting science. In a recent study of *Di Zi Gui* [39], the author argued that many ideas in traditional parenting are in fact similar to the propositions in modern parenting science. For example, trustworthiness is strongly emphasized in *Di Zi Gui*, which is consistent with the emphasis on the importance of gaining

trust from others in the literature of positive youth development. Integrating the ideas in traditional Chinese family instruction books with modern parenting science is undoubtedly interesting yet challenging task to be done. Second, there is a need to develop more assessment tools on Chinese parenting based on imported and indigenous Chinese concepts, such as honoring parents and parental sacrifice.

Third, in view of the unique Chinese cultural emphases (such as emphasis on obedience of children) and Hong Kong ideologies (such as emphasis on academic excellence), there is a need to build up Chinese models of parenting, including its antecedents, concomitants and consequences. For example, it would be important to understand how traditional Chinese parenting beliefs (e.g., emphasis on academic excellence) and contemporary Hong Kong parenting beliefs (e.g., striving for achievement) shape the parenting practices in Hong Kong. Fourth, with time and place as the varying dimensions, it would be exciting to examine how parenting across time (e.g., inter-generational differences in parenting beliefs and practices) and places (e.g., Hong Kong, mainland China, Taiwan and ethnic minority group in China). Comparative studies in different Chinese communities would be important.

Fifth, with long working hours, super-high property price and obsessive emphasis on achievement, there is a great need to understand how parents cope with parental stress in the unique socio-cultural contexts of Hong Kong. In fact, many studies suggest that excessive parenting stress is an emerging family problem in Hong Kong. Sixth, with growing children mental health issues, there is a need to understand the stress and coping of families with children with special needs. Finally, there is a need to step up research to develop parenting education programs in Hong Kong. Although parenting programs flourish in Hong Kong, most of them are not based on well-articulated theoretical models and evaluation is conducted in some isolated programs only [40]. Obviously, there is a need to promote evidence-based parenting policies and programs in Hong Kong.

ABSTRACT

“*Di Zi Gui*” (*Standards for being a good student and child*) is a classic Chinese text outlining the proper behavior of a good student and child. It covers the “desired” behavior of children at home and away from home, things that one should pay attention to in daily life, trustworthiness, love of humanity, learning from people with virtue and compassion, and further study after accomplishing the basic tasks. In this chapter, the basic assertions in different chapters of *Di Zi Gui* were examined with reference to contemporary scientific literature on youth development and parenting. Several observations can be highlighted from the review. First, some assertions in *Di Zi Gui* (such as the emphases on bonding and character) are similar to the emphases in the contemporary youth development literature. Second, some assertions (such as the thought of undermining the rights of children) are not consistent with the contemporary views. Third, *Di Zi Gui* offers novel insights (such as emphasis on the importance of self-cultivation) into the youth development and parenting theories. Finally, there are practical implications of *Di Zi Gui* for youth development and parenting. It is concluded that although *Di Zi Gui* is a classic Chinese text written several centuries ago, some assertions

show striking resemblance to the contemporary scientific findings and it has tremendous implications for contemporary youth development and parenting science and practice.

INTRODUCTION

In many cultures, there are two questions confronting young people, parents, youth workers, allied professionals and policy makers. The first question is what should the developmental “ideals” for children and adolescents should be. In the cultures emphasizing hunting, good physical strengths and independent living skills in children are usually emphasized. On the other hand, as order and social harmony are indispensable to crop growing in the agricultural societies, children are taught to be patient and respect the social norms. The second question is how parents should nurture their children to attain such developmental ideals. Again, different cultural characteristics with reference to the children’s rights or parental power would suggest different strategies in the socialization process.

Regarding the developmental ideals for youth development, different attributes such as positive self-concept, high self-esteem, meaningful engagement and good interpersonal relationship have been proposed by Western theorists. With particular reference to the positive youth development perspective [1-4], the developmental ideals of young people focus on their talents and potentials. According to Catalano, Berglund [5], a thriving young person has the attributes of bonding, resilience, psychosocial competence, self-determination, self-efficacy, positive identity, meaningful life, identification with prosocial norms and meaningful community engagement [6]. According to Lerner, Brentano [7], the developmental ideals for young people include competence, character, connection, confidence, caring and compassion. According to Park and Peterson [8], there are 24 character strengths which can be regarded as the developmental ideals for young people.

Concerning how parents nurture the developmental ideals in young people, it is a question of parenting. In the Western literature, there are two commonly used frameworks of parenting. The first one is based on the work of Baumrind [9] which suggests that there are three types of parenting – authoritarian parenting (absolute control of the child with little freedom), permissive parenting (absolute freedom for the child with little control) and authoritative parenting (appropriate control and freedom for the child). In the second framework proposed by Maccoby and Martin [10], it is proposed that parenting is defined in terms of two dimensions (responsiveness and demandingness). As a result, four types of parenting emerge, including authoritarian parenting (low responsiveness but high demandingness), authoritative parenting (high responsiveness and high demandingness), permissive parenting (high responsiveness but low demandingness) and neglectful parenting (low responsiveness and low demandingness). There are also studies proposing that dyadic and systemic family processes influence adolescent development [11, 12].

In the past few decades, researchers have commonly used the Western models of youth development and parenting to understand Chinese children and parents. In the process, the question of whether the Western notions of youth development and parenting frameworks are applicable to our understanding of Chinese behavior has been raised [13]. One response is that the Western concepts may not be totally applicable and we need to use indigenous Chinese concepts to understand youth development and parenting. In addition, it can be

argued that Chinese writings such as the classics can contribute to our understanding of the developmental ideals for youth development and parenting.

In the traditional Chinese culture, there are writings on the developmental ideals of children and adolescents [14-16]. For example, filial piety was described in the examples in the classic 24 stories of filial piety. The key messages are that the children should obey and serve their parents because their parents gave birth to and take care of them; filial children are blessed by Heaven. Besides, there are many parenting books (“*jia xun*”) which emphasize the developmental ideals of the children and family practice (“*jia gui*”) governing the “proper” behavior of the children [12, 15].

In this paper, we reviewed the Chinese Classic entitled *Di Zi Gui* to understand how the child developmental ideals and parenting were conceived under the traditional Chinese culture. *Di Zi Gui* was written by Li Yu-xiu in the Qing dynasty when Kangxi was the emperor of China. Same as *San Zi Jing* (Three character classic), it takes the form of a three-character verse. The main ideas of *Di Zi Gui* are based on the Confucian thoughts, including the emphases on filial piety, family harmony, self-cultivation of virtues and morality, and maintenance of good interpersonal harmony. In this paper, we will analyze this problem with reference to four topics: a) areas of similarity between the propositions and modern parenting science; b) areas of dissimilarity between the propositions and modern parenting science; c) novel or non-conventional views offered; and d) implications of the propositions about nurturance of the child developmental ideals and parenting. It is noteworthy that there are different versions of *Di Zi Gui*. In this paper, the English version of *Di Zi Gui* is based on the English translation of Pure Land Learning College Association [17]. In this paper, the children refer to the human beings below the age of 18.

REVIEW OF THE OUTLINE

總敘：弟子規 聖人訓；首孝弟 次謹信；汎愛眾 而親仁；有餘力，則學文。

“Outline: *Di Zi Gui* or *Standards for Being a Good Student and Child* is a book that was taught by Chinese saints and sages of the ancient past. The book first teaches us how to be dutiful to our parents, and how to be respectful and loving to our siblings. It then teaches us how to be cautious with all people, matters, and objects in our daily lives; how to be a trustworthy person; and to believe in the teachings of the ancient saints and sages.”

Several observations can be highlighted from the Outline of *Di Zi Gui*. First, the assertions are the teachings of saints and sages of the past. While great men in the past should be respected, it is “authority-based” knowledge rather than “evidence-based” knowledge [18]. Hence, it is questionable whether the related assertions are effective in reality. On the other hand, if the “authority-based” knowledge is consistent with the knowledge derived from contemporary youth development and parenting science, it can be argued that traditional wisdom has contemporary relevance.

Second, family, particularly the father-child relationship and the sibling relationship, is regarded as the central developmental context of the children and adolescents, with filial piety as the cornerstone of child development. A review of the child and adolescent developmental theories shows that many theories are individualistic in nature. For example, Freudian

theories focus on the inner dynamics of human development and cognitive theories focus on the schematic changes throughout the development. While the micro psychological theories have generated much research about the child and adolescent development, they have been criticized for ignoring the environmental influences. Hence, there are theories that focus on how different social systems influence child development. Amongst them, the family-based developmental perspectives focus on the development of children within the family context and how family processes shape the developmental trajectories of adolescent development [19]. *Di Zi Gui* clearly highlights the importance of the family to child development.

Third, the Outline describes the things that one must pay careful attention to. With reference to the expectations about hygiene and daily living, the related measures can be regarded as self-management issues. This feature is quite unique because self-management is an emergent field in the child and youth development in the past few decades. Besides, the focus on “cautions” also hinges on prevention which is an important focus in child and adolescent psychology and prevention science.

Fourth, *Di Zi Gui* emphasizes the importance of trustworthiness of oneself as a cornerstone of selfhood and interpersonal relationship. This point is interesting because trustworthiness (i.e., trust from others) is not a major focus in the contemporary theories of youth development, although self-confidence (i.e., trusting oneself) is commonly emphasized in the positive youth development theories. Obviously, gaining trust from others is much more difficult than gaining trust from oneself.

Fifth, *Di Zi Gui* does not focus on self-cultivation alone. It also emphasizes the importance of loving other human beings. This focus has three unique features. Primarily, it is collectivistic rather than individualistic (i.e., focusing on others is more important than focusing on oneself). Besides, it focuses on the possible contribution of young people to the society. Furthermore, the focus of youth development is on a higher ideal when we cover mankind.

Sixth, it is emphasized that learning from those with virtue and compassion is important. This addresses an important issue about identity formation when the adolescents may model themselves on the significant-others. This point is also related to the adolescent development literature that modeling on positive adults and peers (i.e., bonding) is important for positive youth development [6].

Seventh, one interesting observation from *Di Zi Gui* is that learning from the literature is the last emphasis for youth development. In fact, learning is the last thing when a child has “spare effort”. This is in sharp contrast to the Eriksonian view that children and adolescents should learn the “technological ethos” of the culture. This is also not consistent with the emphasis of the modern societies that formal education is an important developmental task for children and adolescents. Most important of all, this is inconsistent with the contemporary Chinese parenting value, “do not lose at the starting line”.

Finally, the general outline is consistent with the ecological model that different systems should be considered in child and adolescent development. In *Di Zi Gui*, children are taught about the importance of family duties within and outside the family (family system), things that should be cautious (individual system), doing good for other people and loving others (interpersonal system), learning from people with virtue and good reputation (interpersonal system) and learning from literature (historical system).

REVIEW OF CHAPTER 307

入則孝

父母呼，應勿緩。父母命，行勿懶。父母教，須敬聽。父母責，須順承。
冬則溫，夏則清；晨則省，昏則定。出必告，反必面；居有常，業無變。
事雖小，勿擅為；苟擅為，子道虧。物雖小，勿私藏；苟私藏，親心傷。
親所好，力為具，親所惡，謹為去；身有傷，貽親憂，德有傷，貽親羞。
親愛我，孝何難；親憎我，孝方賢。親有過，諫使更；怡吾色，柔吾聲。
諫不入，悅復諫；號泣隨，撻無怨。
親有疾，藥先嘗；晝夜侍，不離床。喪三年，常悲咽；居處變，酒肉絕。
喪盡禮，祭盡誠；事死者，如事生。

“At Home, Be Dutiful to My Parents

When my parents call me, I will answer them right away. When they ask me to do something, I will do it quickly. When my parents instruct me, I will listen respectfully. When my parents reproach me, I will obey and accept their scolding. I will try hard to change and improve myself, to start anew.

In the winter, I will keep my parents warm; in the summer, I will keep my parents cool. I will always greet my parents in the morning to show them that I care. At night I will always make sure my parents rest well. Before going out, I must tell my parents where I am going, for parents are always concerned about their children. After returning home, I must go and see my parents to let them know I am back, so they do not worry about me. I will maintain a permanent place to stay and lead a routine life. I will persist in whatever I do and will not change my aspirations at will.

A matter might be trivial, but if it is wrong to do it or unfair to another person, I must not do it thinking it will bear little or no consequence. If I do, I am not being a dutiful child because my parents would not want to see me doing things that are irrational or illegal. Even though an object might be small, I will not keep it a secret from my parents. If I do, I will hurt my parents' feelings.

If whatever pleases my parents is fair and reasonable, I will try my best to attain it for them. If something displeases my parents, if within reason I will cautiously keep it away from them. When my body is hurt, my parents will be worried. If my virtues are compromised, my parents will feel ashamed.

When my parents do wrong, I will urge them to change. I will do it with a kind facial expression and a warm gentle voice. If they do not accept my advice, I will wait until they are in a happier mood before I attempt to dissuade them again, followed by crying, if necessary, to make them understand. If they end up whipping me, I will not hold a grudge against them.

When my parents are ill, I will taste the medicine first before giving it to them. I will take care of them night and day and stay by their bedside. During the first three years of mourning after my parents have passed away, I will remember them with gratitude and feel sad often for not being able to repay them for their kindness in raising me. During this period, I will arrange my home to reflect my grief and sorrow. I will also avoid festivities and indulgence in food and alcoholic drinks. I will observe proper etiquette in arranging my parents' funerals. I will hold the memorial ceremony and commemorate my parents' anniversaries with utmost sincerity. I will serve my departed parents as if they were still alive.”

Two observations can be highlighted in Chapter 1 of *Di Zi Gui*. First, parents play a superior and dominant role in the family (i.e., parent-centered family). Second, children are expected to fulfil many family duties, particularly for their parents. As far as the child development is concerned, an “ideal” development would be to learn the duties and execute them well. As far as parenting is concerned, children should be taught or socialized to be filial

at home. These observations are consistent with the analyses of Shek and Chan [20] on the attributes of an ideal child.

An examination of the assertions in chapter 1 shows that some of them are consistent with the propositions of the contemporary scientific literature on children and youth development and parenting. First, the focus on respect for parents and duties of children is consistent with the notion of “demandingness” of the notion of authoritative parenting [10]. Instead of providing everything for children as denoted in permissive or indulgent parenting, children are expected to learn and perform their filial piety duties.

Second, the assertions about self-improvement, striving for excellence and perseverance are consistent with the expectations of positive youth development. Primarily, it is conjectured that the duties to be accomplished by the children and adolescents are “doable,” which can be improved through perseverance and a strong motivation to excel. This view is consistent with the positive youth development approach that young people have potential to excel and striving for excellence is possible through perseverance and effort. This view is obviously positive, which sees the children and adolescents as an active agent learning the good things of life and developing virtues [21].

Third, concern for parents is a strong emphasis in this chapter. In terms of family functioning, concerning for one’s parents is a sign of “mutuality” which is basic to the well-functioning families. In the previous studies, it was found that “mutuality” is an important dimension of Chinese family functioning and it has positive relationships to the well-being of Chinese adolescents [22]. Psychologically speaking, showing love to one’s parents will elicit love from the parents. The loving behavior of the children will also foster a warm and reciprocal loving environment within the family.

Fourth, besides taking care of the daily living and physical well-being of their parents, the children are also expected to take care of the “feelings” of the parents (i.e., children should not do things that hurt their parents). This point underscores the importance of cultivation of “empathy” in children and adolescents and the starting point is to practice it within the family. In contemporary adolescent psychology, empathy has been identified as an important factor governing adolescent development [23, 24].

Fifth, the children are expected to follow their family rules, such as telling their parents where they go. In some contemporary family models of family functioning, having family rules is an important sign of family functioning. For example, in McMaster Model of family functioning, it is proposed that “family rules” is an important dimension of effective family functioning. In the parenting literature, following the family rules is an important component of parental behavioral control such as whether the parents know the whereabouts of their children [25, 26]. In fact, parenting workers usually suggest that the families should have clear and reasonable family rules to regulate the behaviors of their children.

Sixth, *Di Zi Gui* asserts that children should love their parents even if their parents hate them. By doing this, the children are learning resilience and forgiveness. Regarding resilience, the children have to learn how to interact with their parents in adversity. Regarding forgiveness, the children have to learn how to accept the wrongdoings of their parents and help them to change. Furthermore, the role of children to dissuade their parents is consistent with some of the family theorists’ propositions that the children can also assume an “adult” role in pointing out the wrongdoings of their parents and inviting them to reflect.

Finally, the assertion on mourning is consistent with the contemporary literature that bereavement takes time [27]. The suggestion of mourning for three years is in fact very

psychological and consistent with the literature that premature termination of mourning is detrimental to one's well-being. The practice of remembering the ancestors also provides psychological support and cultural resources to those family members who are still living (e.g., to complete the good work of the ancestors).

On the other hand, some of the assertions in this chapter are not consistent with the contemporary literature on child development and parenting. Fundamentally, the parent-child relationship is a hierarchical one, with the parents higher than their children. According to Maccoby and Martin [10], this is a form of authoritarian parenting where the children should strictly follow the parental expectations and prescriptions.

The expectation of absolute obedience of children may also be against the United Nations Convention on the Rights of the Child. Besides, contemporary literature highlights the duties of parents instead of children in the socialization process. Some examples are illustrated below:

- **Article 12:** States Parties shall assure to the child who is capable of forming his or her own views the right to express those views freely in all matters affecting the child, the views of the child being given due weight in accordance with the age and maturity of the child.
- **Article 13:** The child shall have the right to freedom of expression; this right shall include freedom to seek, receive and impart information and ideas of all kinds, regardless of frontiers, either orally, in writing or in print, in the form of art, or through any other media of the child's choice.
- **Article 18:** States Parties shall use their best efforts to ensure recognition of the principle that both parents have common responsibilities for the upbringing and development of the child. Parents or, as the case may be, legal guardians, have the primary responsibility for the upbringing and development of the child. The best interests of the child will be their basic concern.

There are two novel points regarding youth development in this chapter. First, one should remember that one's body is inherited from their parents and one should take care of their own body. This view is novel because the emphasis on one's responsibility of taking care of their body is intrinsic to the Western scientific literature. By focusing on the view that one's body is from their parents, one would take into account of the effort that their parents pay in the socialization process. This would reinforce the value of his/her body that the child should take great care of. Besides, this view will also provide an additional perspective for the child to consider when he/she attempts to harm or kill oneself.

Another novel point covered in this Chapter is the notion of having awareness of the feelings of the parents. With growing egocentrism in young people, there is a need to promote empathy in the adolescents. By focusing on the feelings of their parents, it is easier for the children and adolescents to learn empathy. Also, family is a good venue for them to practice empathy. Unfortunately, as Chinese people are quite reserved to express their emotions [28, 29], whether the children can really learn to understand the feelings of their parents is an important question to be considered.

There are four implications of this chapter for child development and parenting. First, young people and parents should develop the belief that young people can excel themselves

and do well with perseverance and motivation as the key processes are involved. Second, promotion of empathy in children can start with helping them to understand the feelings and experiences of their parents. Third, we should reinforce the notion that one's body comes from their parents and one should take care of their own body. This strategy would have important implications for health promotion and prevention of self-harm and suicide. Finally, the notion of the children "advising" their parents is opening up the possibility of more active involvement of children and communication between parents and children.

REVIEW OF CHAPTER 308

出則弟

兄道友，弟道恭，兄弟睦，孝在中。財物輕，怨何生；言語忍，忿自泯。或飲食，或坐走，長者先，幼者後。長呼人，即代叫；人不在，己即到。稱尊長，勿呼名；對尊長，勿見能。路遇長，疾趨揖，長無言，退恭立。騎下馬，乘下車，過猶待，百步餘。長者立，幼勿坐；長者坐，命乃坐。尊長前，聲要低；低不聞，卻非宜。進必趨，退必遲；問起對，視勿移。事諸父，如事父；事諸兄，如事兄。

“Standards for a Younger Brother When Away from Home

If I am the older sibling, I will befriend the younger ones. If I am the younger sibling, I will respect and love the older ones. Only when I can maintain harmonious relationships with my siblings, am I being dutiful to my parents. When I value my familial ties more than property and belongings, no resentment will come between me and my siblings. When I am careful with words and hold back hurtful comments, my feelings of anger naturally die out.

Whether I am drinking, eating, walking, or sitting, I will let the elders go first; the younger ones should follow. When an elder is asking for someone, I will get that person for him right away. If I cannot find that person, I will immediately report back, and put myself at the elder's service instead.

When I address an elder, I should not call him by his given name. This is in accord with ancient Chinese etiquette. In front of an elder, I will never show off. If I meet an elder I know on the street, I will promptly clasp my hands and greet him with a bow. If he does not speak to me, I will step back and respectfully stand aside.

Should I be riding a horse and spot an elder I know walking, I will dismount and pay respect to the elder. If I am riding in a carriage, I will stop, get out of the carriage, and ask if I can give the elder a ride. If I meet an elder passing by, I will stand aside and wait respectfully. I will not leave until the elder disappears from my sight. When an elder is standing, I will not sit. After an elder sits down, I sit only when I am told to do so.

Before an elder, I will speak softly. But if my voice is too low and hard to hear, it is not appropriate. When meeting an elder, I will walk briskly towards him; when leaving, I will not exit in haste. When answering a question, I will look at the person who is asking me the question. I will serve my uncles as if I am serving my parents. I will treat my cousins as if they are my own siblings.”

In chapter 2 of *Di Zi Gui*, some assertions are consistent with the contemporary scientific literature. First, the duties of the elder siblings (to befriend the younger ones) and younger brothers (respect and love the older ones) are clearly defined, which surround the notion of filial piety. If the elder siblings are friendly to the younger ones and the younger ones respect

and concern about the elder ones, it would result in a harmonious family. In fact, in some of the contemporary family therapy models, there is an emphasis on playing the appropriate roles by different family members [25]. In fact, if the members do not play their appropriate roles, the family will become chaotic and cannot function properly. This chapter also focuses on the importance of taking up appropriate roles by the family members.

Second, consistent with the contemporary theories and research on youth development, some important elements of social competence are emphasized in the assertions. Primarily, it is emphasized that one should be careful about words. From an interpersonal communication perspective, appropriate verbal responses such as appreciating or praising others would enrich the relationship. On the other hand, hasty or impulsive words would definitely hurt the interpersonal relationship. Hence, the expectation to “hold back hurtful comments” is in fact positive and even therapeutic in interpersonal relationships.

Third, consistent with the clinical literature, it is asserted that it is important to reduce bitterness and anger [30]. From an intervention point of view, many unsolved human problems stem from bitterness, such as regarding one as unfairly treated or other people being better than us. Similarly, anger also makes interpersonal relationships complicated. In *Di Zi Gui*, it is asserted that through careful verbal communication, anger would subside. Fourth, both assertions and the contemporary scientific literature mentioned controlling one’s bitterness and anger. Fifth, with reference to the propositions of the positive youth development approach, the notion of not to show off in front of elder people is to practice humility, which is regarded as a character strength.

On the other hand, two areas of inconsistency with the contemporary literature can be identified. First, while respect for old people is part of the Chinese culture, it is not consistent with the United Nations Universal Declaration of Human Rights that “everyone is entitled to all the rights and freedoms set forth in this Declaration, without distinction of any kind, such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status”. Obviously, the phrase “or other status” clearly suggests that old and young people should be treated equally in terms of their rights.

The second inconsistency is about “showing off” in front of an elder. It is noteworthy that under the influence of the “self-esteem” movement, children are usually taught to show what they can do and they should appreciate their own talents. Having “shows” in front of other people is commonly encouraged in the contemporary parenting writings because such a behavior can promote self-confidence and self-efficacy in young people, hence contributing to the positive identity in young people.

As far as the novel messages noted in this chapter, there are two distinct observations. First, it is asserted that the family ties should be considered as more important than property and belongings. In other words, a good family is priceless and beyond material calculation (i.e., spiritual emphasis). This point immediately brings the importance to a spiritual level. While many people regard families as important, few theorists have an attempt to assert that the families are more important than material possession.

Second, the saying of “serving your uncles as if they are your fathers and treating your cousins as if they are your brothers” is a good gesture embracing humanity. There are two elements intrinsic to this saying. In the first place, one loves all people instead of categorizing them into “intra-familial” or “extra-familial” people. Besides, one attends to the needs of any people who come into contact with the young person. In terms of Kohlberg’s theory of moral

development, it would be the highest level of moral development involving the universal ethical principle – having universal love for all [31].

There are two implications for child development in this chapter. First, parents should teach their children to say words carefully. With an advance on the Internet, the kids usually give “likes” or leave impulsive comments in the virtual world. Hence, it would be important to promote “careful words” among children while balancing it with encouraging them to express their views. Second, parents can use the family-versus-material possession dilemma to encourage their children to make their choices and understand the reasoning behind [32].

REVIEW OF CHAPTER 309

謹

朝起早，夜眠遲，老易至，惜此時。晨必盥，兼漱口，便溺回，輒淨手。冠必正，紐必結，襪與履，俱緊切。置冠服，有定位，勿亂頓，致污穢。衣貴潔，不貴華，上循分，下稱家。對飲食，勿揀擇，食適可，勿過則。年方少，勿飲酒，飲酒醉，最為醜。步從容，立端正，揖深圓，拜恭敬。勿踐闕，勿跛倚，勿箕踞，勿搖髀。緩揭簾，勿有聲；寬轉彎，勿觸棱。執虛器，如執盈；入虛室，如有人。事勿忙，忙多錯；勿畏難，勿輕略。鬥鬧場，絕勿近；邪僻事，絕勿問。將入門，問孰存，將上堂，聲必揚。人問誰，對以名，吾與我，不分明。用人物，須明求，倘不問，即為偷。借人物，及時還，後有急，借不難。

“Be Cautious in My Daily Life

I will get up each morning before my parents; at night, I will go to bed only after my parents have gone to sleep. When I realize that time is passing me by and cannot be turned back, and that I am getting older year by year, I will especially treasure the present moment. When I get up in the morning, I will wash my face and brush my teeth. After using the toilet, I will always wash my hands.

I must wear my hat straight, and make sure the hooks of my clothes are tied. My socks and shoes should also be worn neatly and correctly. I will always place my hat and clothes away in their proper places. I will not carelessly throw my clothes around, for that will get them dirty.

It is more important that my clothes are clean, rather than how extravagant they are. I will wear only what is suitable for my station. At home, I will wear clothes according to my family traditions and customs. When it comes to eating and drinking, I will not pick and choose my food. I will only eat the right amount; I will not over-eat.

While I am still young, I must not drink alcohol. When I am drunk, my behavior will turn ugly. I will always walk composed, with light and even steps. I will always stand up straight and tall. My bows will always be deep, with hands held in front and arms rounded. I will always pay my respect with reverence.

I will not step on doorsills or stand leaning on one leg. I will not sit with my legs apart or sprawled out. I will not rock the lower part of my body while standing or sitting down. I will always lift the curtain slowly, and quietly. I must leave myself ample space when I turn so I will not bump into a corner.

I will hold empty containers carefully as if they were full. I will enter empty rooms as if they were occupied. I will avoid doing things in a hurry, as doing things in haste will lead to many mistakes. I should not be afraid of difficult tasks, and I will not become careless when a job is too easy.

I will keep away from rowdy places. I will not ask about things that are abnormal or unusual. When I am

about to enter a main entrance, I must first ask if someone is inside. Before entering a room, I must first make myself heard, so that those inside know someone is approaching.

If someone asks who I am, I must give my name. To answer ‘It is me’ or ‘Me’ is not sufficient. Before borrowing things from others, I must ask for permission. If I do not ask, it is stealing. When borrowing things from others, I will return them promptly. Later, if I have an urgent need, I will not have a problem borrowing from them again.”

Regarding chapter 3, there are several areas of consistency that can be highlighted from the assertions. First, the emphasis on personal hygiene (e.g., washing one’s face and brushing one’s teeth after waking up, washing hands after going to the toilet) and posture (i.e., standing and sitting properly) is consistent with the modern guidelines on parenting and the expectation that young people should stay healthy [33]. As promotion of physical health of children is emphasized in modern medicine and parenting, it is interesting to note that this was highlighted in *Di Zi Gui* roughly three centuries ago. Second, the focus on tidiness in the dress code is also emphasized in modern parenting and professions (such as occupational therapy) because tidiness in clothing is a social skill. Dressing in a tidy and decent manner can create a sense of “positive social identity” for the child, which would eventually create self-confidence in young persons.

Third, appropriate eating and drinking are also highlighted in modern child care and developmental psychology. Having good eating habits does not only ensure nutritional needs of the child; it also promotes a “non-choosy” habit in children. Fourth, there are also some assertions related to “accident prevention” (to lift the curtain slowly and quietly and not to bump into corners). This is in line with the literature on accident prevention [34].

Fifth, regarding risk behavior, it is asserted that young children should not drink alcohol and the negative consequence of drinking too much alcohol is emphasized. This point closely echoes to the proposition of prevention science that children should stay away from alcohol. Sixth, regarding the expectation that the children should keep away from the rowdy places, this view is consistent with prevention science that children stay away from the rowdy places, which are commonly regarded as risk factors precipitating risk behavior in the adolescents [35].

The assertion that is not consistent with the contemporary knowledge is on the expectation that the children should dress in a tidy manner. Besides the argument that the children have the right to dress in the way they want, there are also views suggesting that the non-conventional ways of dress are signs of creativity and innovation. Besides, the assertion that one should avoid doing things in a hurry manner is somehow not consistent with the contemporary view that one should learn multi-tasking (i.e., doing many things at one time is actually a merit).

There are several unique features of the assertions in this chapter. First, the focus on child development is quite holistic in nature, ranging from physical health to social health. Second, the focus on cleanliness rather than extravagance underscores the importance of the non-materialistic values. Third, setting rules on borrowing can promote social competence of young people. Fourth, it is asserted that children should treasure time which is not commonly described in the literature on child development.

The implications of this chapter on child development are multiple. First, the parents should nurture the self-management skills in children in different domains. Second, the children should develop a sense of treasuring time [36].

REVIEW OF CHAPTER 310

信

凡出言，信為先，詐與妄，奚可焉。話說多，不如少，惟其是，勿佞巧。奸巧語，穢污詞，市井氣，切戒之。見未真，勿輕言，知未的，勿輕傳。事非宜，勿輕諾，苟輕諾，進退錯。凡道字，重且舒，勿急疾，勿模糊。彼說長，此說短，不關己，莫閒管。見人善，即思齊，縱去遠，以漸躋。見人惡，即內省，有則改，無加警。唯德學，唯才藝，不如人，當自礪。若衣服，若飲食，不如人，勿生感。聞過怒，聞譽樂，損友來，益友卻。聞譽恐，聞過欣，直諒士，漸相親。無心非，名為錯，有心非，名為惡。過能改，歸於無，倘揜飾，增一辜。

“Be Trustworthy

When I speak, honesty is important. Deceitful words and lies must not be tolerated.

Rather than talking too much, it is better to speak less. I will speak only the truth, and I will not twist the facts.

Cunning words, foul language, and philistine habits must be avoided at all costs. What I have not seen with my own eyes, I will not readily tell to others. What I do not know for sure, I will not easily pass on to others.

If I am asked to do something that is inappropriate or bad, I must not agree to it. If I do, I will be doubly wrong. I must speak clearly and to the point. I must not talk too fast or mumble.

Some like to talk about the good points of others, while some like to talk about the faults of others. If it is none of my business, I will not get involved. When I see others do good deeds, I must think about following their example. Even though my own achievements are still far behind those of others, I am getting closer.

When I see others do wrong, I must immediately reflect upon myself. If I have made the same mistake, I will correct it. If not, I will take extra care to not make the same mistake. When my morals, conduct, knowledge, and skills seem not as good as those of others, I will encourage myself to be better.

If the clothes I wear, and the food I eat and drink are not as good as that of others, I should not be concerned. If criticism makes me angry and compliments make me happy, bad company will come my way and good friends will shy away.

If I am uneasy about compliments and appreciative of criticism, then sincere, understanding, and virtuous people will gradually come close to me. If any mistake I make is inadvertent, it is merely a mistake. If it is done on purpose, however, it is an evil act. If I correct my mistake and do not repeat it, I no longer own the mistake. If I try to cover it up, I will be doubly wrong.”

Consistent with the positive youth development perspective, honesty, non-tolerance of deceitful words and lies, speaking the truth and keeping one's promise is emphasized in the assertions in this chapter [37]. Second, the assertions that speaking should be clear and messages should be succinct are consistent with the principles underlying social competence. Finally, the assertion that one should not be concerned about one's food and clothes not as good as others' is consistent with the view of the cognitive-social perspective that one should not have unnecessary competition.

There is one area that is inconsistent with the contemporary literature – one should not be angry about criticisms and happy about compliments while one should appreciate criticisms

and be uneasy about compliments. This assertion is not consistent with the psychological principle that one should be true to one’s feelings and one should feel good if they receive compliments from others.

There are several unique points covered in this chapter. First, one should not use cunning words and foul language. Second, it is emphasized that one should be careful about witnessing and should not gossip about others. Third, the assertions emphasize self-reflection. Fourth, while one should not compare with others in terms of clothes and food, we should compare with others in terms of morals, conduct, knowledge and skills.

The present chapter has several implications for youth development and parenting. First, young people should learn to use their words in a careful and decent manner. Unfortunately, the general public tend to endorse the use of foul language and regard it as “entertaining.” Second, no gossip is good for child development because it creates hatred, misunderstanding and even bullying. Third, children should be encouraged to reflect, including both the good things and bad things about themselves. Finally, learning not to compare with others on material possession is needed because the contemporary societies are very materialistic in nature. On the other hand, sensitivity about one’s virtues relative to others for improvement is helpful to child development.

REVIEW OF CHAPTER 311

汎愛眾

凡是人，皆須愛；天同覆，地同載。行高者，名自高；人所重，非貌高。才大者，望自大；人所服，非言大。己有能，勿自私；人有能，勿輕訾。勿諂富，勿驕貧；勿厭故，勿喜新。人不閒，勿事攪；人不安，勿話擾。人有短，切莫揭；人有私，切莫說。道人善，即是善，人知之，愈思勉。揚人惡，即是惡，疾之甚，禍且作。善相勸，德皆建；過不規，道兩虧。凡取與，貴分曉；與宜多，取宜少。將加人，先問己；己不欲，即速已。恩欲報，怨欲忘；報怨短，報恩長。待婢僕，身貴端，雖貴端，慈而寬。勢服人，心不然，理服人，方無言。

“Love All Equally

Human beings, regardless of nationality, race, or religion – everyone – should be loved equally. We are all sheltered by the same sky and we all live on the same planet Earth. A person of high ideals and morals is highly respected. What people value is not based on outside appearance.

A person’s outstanding abilities will naturally endow him with a good reputation. Admiration from others does not come from boasting or praising oneself. If I am a very capable person, I should use my capabilities for the benefit of others. Other people’s competence should never be slandered.

I will not flatter the rich, or despise the poor. I will not ignore old friends, only taking delight in new ones. When a person is busy, I will not bother him with matters. When a person’s mind is not at ease, I will not bother him with words.

If a person has a shortcoming, I will not expose it. If a person has a secret, I will not tell others. Praising the goodness of others is a good deed in itself. When people are being praised and approved of, they will be encouraged to try even harder.

Spreading rumors about the wrongdoings of others is a wrongdoing in itself. When the harm done has reached the extreme, misfortunes will surely follow. When I encourage another to do good, both of our virtues are built up. If I do not tell another of his faults, we are both wrong.

Whether I take or give, I need to know the difference between the two. It is better to give more and take less. What I ask others to do, I must first ask myself if I would be willing to do. If it is not something I would be willing to do, I will not ask others to do it.

I must repay the kindness of others and let go of my resentments. I will spend less time holding grudges and more time paying back the kindness of others. When I am directing maids and servants, I will act honorably and properly. I will also treat them kindly and generously. If I use my influence to make them submissive, their hearts will not be with me. If I can convince them with sound reasoning, they will have nothing to object to.”

The present assertions on loving each other and contribution to society are consistent with the emphases on “compassion” and “contribution” under the positive youth development approach. Besides, the expectation of not slandering the ability of other people is in line with the principle of respecting others in the positive youth development literature. Furthermore, the notions of kindness to others and forgiveness are also in line with the spirit behind spirituality. Finally, using reasoning instead of authority to make people submissive is consistent with the principles of modern psychology.

There are several unique emphases in this chapter. First, outer appearance is not as important as ideals and morals (i.e., non-material attributes are more important than material attributes). Second, young people should not discriminate against others based on their material possession and social status. Third, children should learn to praise the goodness of others but should not gossip about the rumors of others.

The assertions in this chapter have several implications for youth development and parenting. First, cultivation of a sense of love for others is important. Second, it is helpful to teach the children about the importance of inner virtues instead of outer appearance. Third, using one’s ability to serve the society is a good developmental goal. Fourth, accepting people with different backgrounds and treating them equally. Fifth, praising others and do not gossip about others’ faults [5].

REVIEW OF CHAPTER 312

親仁

同是人，類不齊；流俗眾，仁者希。果仁者，人多畏；言不諱，色不媚。能親仁，無限好；德日進，過日少。不親仁，無限害；小人進，百事壞。

“Be Close to and Learn from People of Virtue and Compassion

We are all human, but we are not the same. Most of us are ordinary; only a very few have great virtues and high moral principles. A truly virtuous person is greatly respected by others. He will not be afraid to speak the truth and he will not fawn on others.

If I can be close to and learn from people of great virtue and compassion, I will benefit immensely. My virtues will grow daily and my wrongdoings will lessen day by day. If I choose not to be close to and learn from people of great virtue, I will suffer a great loss. People without virtue will get close to me and nothing I attempt will succeed.”

Three interesting observations can be highlighted in this chapter. First, the assertion that few of us have great virtues and high moral principles is consistent with the view that few of us can proceed to the post-conventional level [31]. Second, it underscores the importance of moral courage of speaking the truth and not fawning on others [8]. Finally, the teaching of being close to people with great virtue and compassion but staying away from people without virtue is consistent with the principle of “bonding” that healthy adults and peers are important to the healthy development of children.

REVIEW OF CHAPTER 313

餘力學文

不力行，但學文，長浮華，成何人。但力行，不學文，任己見，昧理真。
讀書法，有三到，心眼口，信皆要。方讀此，勿慕彼，此未終，彼勿起。
寬為限，緊用功，工夫到，滯塞通。心有疑，隨札記，就人問，求確義。
房室清，牆壁淨，几案潔，筆硯正。墨磨偏，心不端；字不敬，心先病。
列典籍，有定處；讀看畢，還原處。雖有急，卷束齊，有缺壞，就補之。
非聖書，屏勿視，蔽聰明，壞心志。勿自暴，勿自棄，聖與賢，可馴致。

“Be Close to and Learn from People of Virtue and Compassion

If I do not actively practice what I have learned, but continue to study on the surface, even though my knowledge is increasing, it is only superficial. What kind of person will I be? If I do apply my knowledge diligently, but stop studying, I will only do things based on my own opinion, thinking it is correct. In fact, what I know is not the truth.

There are methods to study correctly. They involve concentration in three areas: my mind, my eyes, and my mouth. To believe in what I read is equally important. When I begin to read a book, I will not think about another. If I have not completed the book, I will not start another.

I will give myself lots of time to study, and I will study hard. If I devote enough time and effort, I will thoroughly understand. If I have a question, I will make a note of it. I will ask the person who has the knowledge for the right answer.

I will keep my room neat, my walls uncluttered and clean, my desk tidy and my brush and ink stone properly placed. If my ink block is ground unevenly, it shows I have a poor state of mind. When words are written carelessly, showing no respect, this shows my state of mind has not been well.

My books should be classified, placed on the bookshelves, and in their proper places. After I finish reading a book, I will put it back where it belongs. Even if I am in a hurry, I still must neatly roll up and bind the open bamboo scroll I have been reading. All missing or damaged pages ought to be immediately repaired.

If it is not a book on the teachings of the saints and sages, it should be discarded and not even looked at. Such books can block my intelligence and wisdom, and will undermine my aspirations and sense of direction. Neither be harsh on myself, nor give up on myself. To be a person of high ideals, moral standards and virtue is something we can all attain in time.”

Several observations in this chapter are consistent with the scientific literature. First, the urge to continue studying is in line with the principle of life-long learning. Second, the propositions on the methods of learning (involvement of mind, eyes, mouth and

concentration) and devotion of time and effort are consistent with the work of educational psychology. Third, asking people when one has questions is also consistent with the social support literature.

Regarding the key to studying, the assertions can be regarded as not comprehensive enough because besides effort, concentration and involvement, there are many other factors. For example, those with learning difficulties may exert effort without academic success. Besides, the suggestion that one should not read the books not written by saints and sages is not consistent with the contemporary view that one should read any books widely with different viewpoints.

There are four unique messages in this chapter. First, it focuses on the importance of practice and learning. Second, the emphasis on the tidiness in studying is quite novel. Third, the last assertion that one should not be harsh or give up on oneself is very humanistic. Furthermore, the promise that one can be a person with high moral standards is also empowering in nature.

The assertions have several implications for youth development and parenting: First, do not simply focus on the superficial study; practice is important. However, practice without studying is also no good. Second, never be harsh on oneself or give up. Third, have a belief that if one tries hard, high ideals and virtue can be attained.

DISCUSSION

The pioneer review attempts to examine *Di Zi Gui* with reference to four issues: a) the consistency between the related assertions and the views of the contemporary youth development literature; b) the inconsistency between the related assertions and the contemporary views; c) the novel or alternative views on youth development and parenting; and d) the implications of *Di Zi Gui* for youth development and parenting.

Although *Di Zi Gui* was written several centuries ago, some of its assertions have striking consistency with the contemporary models of youth development and parenting. For example, the focus on physical health and character development is in line with the contemporary models on youth development and parenting (e.g., Australia National Health and Medical Research Council [38]). Hence, it can be concluded that traditional wisdom does have contemporary scientific support. Nevertheless, some of the assertions, such as following traditions without doubt, one should only read sacred books and the de-emphasis of the rights of children are not consistent with the contemporary views of youth development and parenting. Furthermore, *Di Zi Gui* offers some novel ideas, such as the emphasis on the inner qualities rather than the external attributes of a person and the importance of social competence, such as not to gossip about others and accept the wrongdoings of others. Finally, *Di Zi Gui* has useful implications of the assertions for youth development and parenting.

Three observations can be further highlighted in the present review. First, *Di Zi Gui* shows the fundamental attributes of the youth developmental ideals and parenting of the traditional Chinese culture. According to Shek and Lai [39], traditional Chinese families had a strong emphasis on family harmony, as exemplified in the popular sayings of “*yi he wei gui*” (harmony is golden) and “*jia he wan shi xing, jia shuai kou bu ting*” (if a family lives in harmony, everything will prosper; a family will wither if there are a lot of quarrels). To

achieve family harmony, every family member had the obligations and duties defined by the five cardinal relationships [14]. With a specific focus on children, the children were taught about the importance of “*bai shan xiao wei xian*” (filial piety ranks the top in all behaviors). An ideal family in the traditional Chinese culture was characterized by “*fu ci zi xiao, xiong you di gong*” (kind father and filial son, affectionate brothers).

The assertions in *Di Zi Gui* are also consistent with the attributes of the traditional Chinese socialization practice summarized by Yang [16]. These attributes included dependence training (children should obey their parents and depend on them), conformity training (interpersonal harmony should be valued but interpersonal conflicts should be avoided), self-suppression training (training of self-inhibition and self-sacrifice), humility training (one should learn to be humble), contending mentality (one should accept one’s situation), punishment orientation (harsh punishment for non-conforming behavior), and parent-centeredness (parents determine the socialization goals).

Second, the present review highlights a question that should be further examined – is the teaching of the traditional Chinese classics useful? With the advance of Western technology and industrial might, many people have held the belief that the traditional Chinese teaching is not useful. Some may even outright reject the traditional Chinese views and uncritically accept the usefulness of the Western ideas. However, there are two problems of a total abandonment of the traditional Chinese ideas. First, there is teaching in the Chinese classics which has been practiced for a very long time. As shown by the present review, such cultural wisdom is in fact consistent with the contemporary scientific literature. Second, when one views the Western theories and findings, it is important to ask how such ideas fit into the cultural context of China. For example, while the Western emphasis on the children’s rights is important, the duties and obligations of children are relatively neglected. At the same time, one should ask whether the traditional Chinese teaching can effectively be used in the contemporary world.

Third, to answer the question of whether the traditional Chinese teaching is useful or not, we have conducted research on two levels. For example, Shek and Sun [15] pointed out that Chinese parental control is a mixture of behavioral control (e.g., high parental expectation and monitoring) and psychological control (e.g., guilt induction). How this strange mixture might be translated to motivation to excel in academic excellence is an important issue to be addressed. Therefore, future research should focus on how the traditional Chinese teaching on youth development and parenting is aligned with the contemporary scientific theories and findings at the conceptual level.

Finally, it is interesting and important to ask how the elements of *Di Zi Gui* can possibly be utilized in the youth development and parenting programs. In particular, with reference to the growing emphasis on character education for young people, the teaching of *Di Zi Gui*, such as striving for excellence in morality and focus on the inner quality instead of the outer appearance of a person, has obvious practical implications. Most important of all, it is interesting to ask whether the children under the influence of *Di Zi Gui* thrive better than the children without the influence of *Di Zi Gui*.

ACKNOWLEDGMENTS

An earlier version of this paper was presented at the International Conference on “The Relevance of the Classics under the Conditions of Modernity: Humanity and Science” organized by the Faculty of Humanities, The Hong Kong Polytechnic University in October 2017. This chapter is based with permission on papers adapted from a special issue published in the *International Journal of Child and Adolescent Health* 2019;12(4) issue.

ABSTRACT

Adolescence is a period during which adolescents and their parents have to re-define the ways of interaction and resolution of parent-adolescent conflicts. As such, how to help adolescents learn the ways to interact with their parents in a healthy manner is an important question to be considered. Adopting a positive youth development perspective, it is argued that promotion of psychosocial competencies of adolescents can help adolescents to develop better emotional and social competencies, which would eventually promote family cohesion and harmony. In this paper, several units in the Project P.A.T.H.S. with reference to bonding and resilience are outlined to illustrate how positive youth development programs may help to promote family quality of life amongst families with adolescent children.

INTRODUCTION

Adolescence is a transitional stage full of challenges. During this critical period, different risk factors, such as undesirable peer influences and low self-efficacy, lead to poor adolescent

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

development. At the same time, different protective factors, such as support from family as well as significant carers, school, and peers, can help adolescents to build up their competences and character strengths. Among these protective factors, family serves as one vital factor for adolescent development, especially a family with good family relationship and a high level of functioning [1].

Family functioning refers to “the quality of family life at systemic and dyadic levels and concerns wellness, competence, strengths, and weaknesses of a family” [2]. A high level of mutuality of the family, good conflict management within the family, and good communication are three main dimensions of family functioning [3]. A well-functioned family can always promote the well-being for family members. For example, high quality of parent-child communication can prevent children from engaging in different risk behaviors, and it also benefits their psychological health [4, 5]. In fact, a positive parent-child relationship does not only promote adolescent development [6], but also benefits the functioning of the whole family. If both parents and the child are satisfied with their relationship, this would help to promote mutuality of the family as well as to minimize the negative consequences generated from parent-adolescent conflicts.

Theoretically, bonding and mutual trust between parents and children are generated from a good parent-child relationship [7, 8]. Bonding is the “attachment behavior held to characterize human beings from the cradle to the grave” [9]. It refers to the emotional attachment between an individual and others, such as parents, siblings, schoolmates, peers, and teachers. There is a large body of literature supporting the notion that family bonding can benefit self-esteem, problem solving skills and other competencies in children and adolescents [7, 10]. Family bonding can also nurture children and adolescent resilience and help seeking practice. Resilience is an important character for individuals to adapt to challenging events in a healthy way and bounce back from difficulties [11]. Nurturing resilience is one of the major tasks during adolescence [12]. Research showed that bonding contributes to the enhancement of resilience among the youths [13-15]. Moreover, building up a healthy help-seeking style can prevent adolescents from using inappropriate ways to tackle their problems. Different researchers argued that family bonding can facilitate adolescents to have appropriate help-seeking practice [16, 17].

However, as the society changes and evolves, there are more and more obstacles to the development of family bonding and parent-child relationships. For example, parents’ long working hours and stressful work life are some factors which impede the parent-child relationship, especially in Hong Kong [18-20]. Most Hong Kong parents are burdened by unreasonable long working-hours, and it is not easy for them to spend time to communicate with their children or provide advice. Therefore, misunderstandings within the family and parent-adolescent conflicts are likely to occur. Furthermore, it may also affect the help-seeking practice of adolescents as they are not able to or willing to seek help from their parents or other family members.

To solve the above problems, family education is one effective way. However, it is not easy to implement family education for parents due to their limited time and resources [21]. As such, another possible way is to start the prevention work in the school context, such as enhancing students’ understandings of their parents, equipping positive communication skills, and nurturing their healthy help-seeking style.

In this chapter, a positive youth development program entitled the Project P.A.T.H.S. is used to demonstrate how school programs can be implemented in the school context to promote family life for secondary school students.

PROJECT P.A.T.H.S.

Project P.A.T.H.S. is the first and only systematic youth development program in Asia with positive evaluation findings based on multiple evaluation strategies [22, 23]. This project was launched in 2005 with four main components, including (i) curriculum development; (ii) interactive training for frontline teachers and social workers; (iii) implementation of the program in secondary schools; and (iv) systematic evaluation.

For curriculum development, 271 teaching units were developed for Secondary 1 to Secondary 3 students, which included 120 original teaching units, 60 special units (focus on 5 special themes on adolescent developmental issues), 61 updated teaching units, and 30 revamped teaching units. The design of the teaching units included different interactive learning activities and multi-media activities. The package for each teaching unit contains a detailed lesson plan together with all teaching materials, such as worksheets, PPT slides, guidelines for students' discussion or sharing, and different multi-media activities (e.g., video clips, mobile app, and computer games). An interactive learning platform has been established to facilitate students' learning through online interactive activities, such as online polling, drawing activities. To facilitate teacher's teaching and preparation for the class, procedures of each activity are clearly listed in the lesson plan, together with teaching tips for the teacher's reference. Also, a video clip for each original unit has been recorded by real frontline teachers for sharing with teachers and social workers. In addition, to share practical ideas amongst teachers, ten video clips have been developed which are based on different themes of teaching skills and classroom management skills. Since 2005, more than 357,839 students (with 674,637 man-times) participated in this project from more than 360 schools and agency units.

As training is the backbone for successful program implementation, the P.A.T.H.S. Project emphasizes the importance of providing quality training for teachers before they start teaching the teaching units. In the past 15 years, around 300 interactive training workshops have been conducted for 9,400 teachers, social workers, or other related professionals. Also, a well-designed e-learning program has been developed by the research team. Participants can join a 20-hour e-learning program (for each grade) to become qualified teachers.

Finally, a systematic evaluation design was conducted to generate useful information for researchers and frontline teachers on the effectiveness of the program as well as areas to be improved. In the Project P.A.T.H.S., a comprehensive evaluation design using multiple methods which included both qualitative and quantitative research elements. All results were well documented and published [22-27]. In this paper, three units are used as examples to demonstrate how the P.A.T.H.S. Project helps to promote family life of adolescents through classroom learning activities.

RESILIENCE

To build up good resilience, family belongingness is one important external protective factor for optimal adolescent development. To help secondary students promote this PYD quality, the Research Team developed a teaching unit named “Those were the days” (RE1.1) for Secondary One students [28; Appendix 1). The objectives of this unit are helping students:

- To learn to seek help from different people under different circumstances.
- To understand parents’ communication style and thus promote trust toward parents and a sense of belonging within the family.

In this teaching unit, through group and classroom discussion, students can learn to reduce their hesitation and uneasiness when they seek help from parents. It is expected that students can recognize the potentially positive messages behind parents’ words and actions. The lesson plan and teaching materials are presented to Appendix 1.

BONDING

As discussed in the previous section, family bonding is one source of emotional attachment and support for adolescents in facing challenges and difficulties. In this paper, two units are presented to demonstrate how to help secondary students to build up a stronger bonding with their parents through classroom learning activities.

The first unit is entitled “What can I do for my family?” (BO2.1) which is a unit developed for Secondary 2 students (29; Appendix 2). The objectives of this unit are helping students:

- To recall the occasions on which students received care from their parents.
- To explore their roles playing at home and to enhance motivations to contribute to families.

In this teaching unit, teaching activities have been developed to promote student reflection. At the beginning of this unit, students are asked to describe their meanings of “family” and share their ideas of an ideal family. After this, two activities are developed for students to reflect and explore how they can contribute to their own families. The lesson plan and teaching materials are outlined in Appendix 2.

Another teaching unit is entitled “Parents’ message” (BO2.2) which was developed to equip students’ communication skills with their parents, and to strengthen parent-child relationships (30; see Appendix 3). The objectives of this unit are helping students:

- To analyze parents’ messages from people-oriented and task-oriented points of view.
- To demonstrate proper response to parents’ messages and establish a good relationship with the parents.

In this unit, students are divided into different groups for discussion. A video clip is included to help students to reflect parents' underlying messages from different scenarios, and learn to use appropriate responses towards parents in order to avoid miscommunication with their parents.

DISCUSSION

In this chapter, we present three units of the Project P.A.T.H.S. to illustrate how positive youth development programs can help to promote family life quality in adolescents. As family life education has been commonly conducted within the framework of parent education, it is important to consider family life education from another side of the coin – promoting family life quality in adolescents.

There are several observations deserving our attention. First, it is important to promote the psychosocial competence of adolescents as a strategy to promote the quality of their family life. The basic reasoning is that by promoting the psychosocial competence of young people, their relationships with the parents would improve, hence promoting the family quality of life. Second, the units illustrate the feasibility of developing curricular-based training programs to promote family quality of life of adolescents. As there are few validated PYD programs in different Chinese contexts, the units developed can help professionals who would like to promote family quality of life in adolescents. Third, as there is a general drop in PYD attributes in early adolescence [1, 31], there is a need to devise ways to promote the PYD development of early adolescents. The Project P.A.T.H.S. units provide a way to nurture the PYD attributes in adolescents. Finally, although there is support that the P.A.T.H.S. programs can help to promote holistic youth development [27, 32], there is a need to further explore how improvement in PYD might contribute to improvement in family quality of life.

APPENDIX 1: UNIT RE1.1 “THOSE WERE THE DAYS”

Construct

- Resilience

Target Participants

- Secondary One students

Unit Aims

- 1) To learn to seek help from different people under different circumstances
- 2) To understand parents' communication style and thus promote trust toward parents and a sense of belonging within the family

Learning Targets

- 1) To learn to seek help from different people when encountering different types of problems
- 2) To recognize the potentially positive messages behind parents’ words and actions

Teaching Materials

Group Worksheet: Appendix 1
“Those Were the Days”
Worksheet: Appendix 2
“The Message Behind” (Version A and Version B)
Growth Puzzle: Appendix 3

Teaching Methods

- Group Discussion
- Class Discussion

Implementation Plan (30 Minutes)

Primary Activity
Secondary Activity

Activity	Procedures
I. Warm-up activity (2 minutes)	Begin this unit by asking: 1. Did you come across any problem(s) this week (month)? 2. Was there anyone you can turn to when you were in trouble?
II. Group discussion: Those Were the Days  (15 minutes) Teaching materials <i>Appendix 1</i>	Aim: To learn to seek help from different people when encountering different types of problems 1. Divide students into 8 groups and distribute the Group Worksheets (<i>Appendix 1</i>). 2. Briefly introduce the content. Allow 5 minutes for discussion. 3. Discussion question: “When you have the following problems, who will you talk to or seek help? Write down your reasons.” 4. Ask students to report their responses. 5. Conclude and highlight: i. When one is in trouble, s/he can look for help, rather than facing it alone. ii. There are many options to the same problem. It differs from person to person. iii. Despite the options, students should think carefully and decide who can give the most positive support when they look for help. iv. Students tend to share with others when they are happy but not when they are troubled. Ask them to consider the reasons behind this phenomenon.

Activity	Procedures
III. Class discussion: The Message Behind  (5 minutes) Teaching materials <i>Appendix 2</i>	Aim: To understand parents' way of expression or communication style 1. Distribute the Worksheets (<i>Appendix 2</i>). 2. Some common responses made by parents are shown in the cartoons. By asking students to fill in the answers, they can explore parents' intention and recognize the "real" message. 3. The aim of this exercise is to eliminate any hesitation and uneasiness among students when they ask for help from people of authority (such as parents), and let them realize their parents' concern. Show students the fact that a lack of communication skills and pressure from life may contribute to parents' seemingly harsh attitude. Ask students to try to think in the other's shoes. 4. Ask students to share their experiences briefly.
IV. Conclusion (3 minutes)	1. Encourage to ask for help when they are in trouble. 2. Aim at dissociating students from the thoughts that inhibit them from asking for help. 3. Lead students to consider who they can seek help apart from parents when they are in trouble.
V. Self-reflection (5 minutes) Teaching materials <i>Growth Puzzle</i>	1. Distribute the Growth Puzzle and engage students in self-reflection. 2. Praise students for their participation during the lesson.

Teaching Tips

1. "Those were the days"	- Conduct a poll and write down the answers on the blackboard. - If the choices students made are highly similar, tell them that they can ask for help from different people according to the nature of the problem (e.g., seek help from parents if their problem is related to money; from social worker / counselor if it is related to emotions). - If the person they choose to talk to has big differences, instructors can point out the result is normal due to differences in students' backgrounds and psychological conditions. - Encourage those who always opt to handle problems alone to look for help from others. - If students fail to express themselves in writing, ask them to report verbally. - Put down the reasons on the blackboard that students give as examples, e.g. that the one I talk to always pointing out my problems is sincere; 2) that they are caring and considerate; 3) that they are knowledgeable. - If students are more mature, instructors may modify the worksheet, to use "x" to indicate specific people they would not seek help from. This may lead to an interesting discussion on "why / why not."
2. "The message behind"	- Choose version A (local Chinese-based) or version B (international-based) for <i>Appendix 2</i>, depending on the cultural background of students. - For students with a complicated family background or having a poor relationship with their parents, instructors should pay special attention to their emotional responses. - Encourage students to think from the point of view of their parents. The aim of doing this does not mean that they need to comply with their parents' directions, but focus on understanding parents' difficulties. It also trains students to be more considerate and encourages them to express to parents their feelings in a constructive and helpful way, and talk to teachers and counselors when necessary. - Invite students who are mentally more mature to join in a role-play. It can not only lead to a better participation, but can also allow students to experience their parents' feelings. During the process, instructors should ask students to first think about the intention behind parents' words, and then what they may, as daughters and sons, say in response. Ask students to consider if their response is constructive to a better relationship or not.

Supplementary Activity (Optional)

Activity	Content	Recommendations
Letters of love	Aim: To establish a good relationship with parents and enhance a sense of belonging toward family Ask students to write a letter to their parents after class. Ask them to express their appreciation or gratitude to their parents.	If students have difficulties in expressing themselves, instructors can discuss together with them. Doing so can also promote the relationship between the parties.

A 1.1. Group Worksheet: “Those Were the Days”

Group:

Dear fellow students, when you have the following problems, who will you talk to or seek help? Why?

When I have problems related to...	I will talk to / seek help from: (Can choose more than one)
Study (e.g., fail to catch up with the lesson, having lots of difficulties when doing homework) 	I will talk to / seek help from: (Can choose more than one) ☐ Friends ☐ Social worker / Counselor ☐ Teachers ☐ Parents ☐ Myself ☐ Others: _____ Why? _____
Emotion (e.g., unhappy, angry) 	☐ Friends ☐ Social worker / Counselor ☐ Teachers ☐ Parents ☐ Myself ☐ Others: _____ Why? _____
Money 	☐ Friends ☐ Social worker / Counselor ☐ Teachers ☐ Parents ☐ Myself ☐ Others: _____ Why? _____
Sharing of satisfaction and happiness (e.g., getting a good mark; given an award) 	☐ Friends ☐ Social worker / Counselor ☐ Teachers ☐ Parents ☐ Myself ☐ Others: _____ Why? _____

A 1.2. Worksheet: “The Message Behind” (Version A)

Name: _____

Consider what parents really mean in the following dialogues:

Dialogue 1 	Dialogue 2 
When you are working hard on preparing for an exam... What Mom may really mean: _____ _____	You do not need to go to school the next day, so you want to tell your parents you wish to go out with your friends in the evening... What Mom may really mean: _____ _____
Dialogue 3 	Dialogue 4 
You want to buy an online game, but you don't have enough money... What Dad may really mean: _____ _____	Father comes back every night at around 11:00p.m... What Dad may really mean: _____ _____

A 1.3. Worksheet: “The Message Behind” (Version B)

Name: _____

Consider what parents really mean in the following dialogues:

Dialogue 1	Dialogue 2
	
When you want to join a three-day camp... What Dad may really mean: _____ _____	On Friday evening... What Mom may really mean: _____ _____
Dialogue 3	Dialogue 4
	
You are going out with a friend and plan not to have dinner at home tonight... What Mom may really mean: _____ _____	Father comes back every night at around 10:00pm... What Dad may really mean: _____ _____

A 1.4. Growth Puzzle

Name:

Class:

Date:

Classwork:

1. List out 3 necessary conditions for overcoming difficulties and those functions

2. When you are facing some difficulties, who do you want to ask for help? Why?

3. Recall the experience of your parents helping you to solve problems. Which ways of solving problems have you learned from them?

4. Are there any psychological barriers (e.g. feel embarrassed), which stop you to ask for help? What methods can help you to break the barriers?

5. Do you agree with the assumption that "seeking helps means being weak"? Why?

6. How important does "having hopes" affect you to face the difficulties and solve the problems?

APPENDIX 2: UNIT BO2.1 "WHAT CAN I DO FOR MY FAMILY?"**Construct**

Bonding

Target Participants

Secondary Two students

Unit Aims

To make more contributions at home so as to strengthen relationship with the family

Learning Targets

- 1) To recall the occasions on which students received care from their parents
- 2) To explore the roles play at home and to enhance motivation to contribute to families

Teaching Materials

PowerPoint Slides: Appendix 1
 “Family Album”
 PowerPoint Slides: Appendix 2
 “What Can I Do for My Family?”
 Worksheet: Appendix 3
 “What Can I Do for My Family?”
 Growth Puzzle: Appendix 4

Teaching Methods

- Class Sharing
- Personal Reflection

Implementation Plan (30 Minutes)

Primary Activity
 Secondary Activity

Activity	Procedures
I. Warm-up activity (5 minutes) Teaching materials <i>Appendix 1</i>	1. Begin this unit by playing the PowerPoint Slides (<i>Appendix 1</i>) without instruction. 2. When the slides are finished, ask students: i. What does “family” mean to you? ii. Describe your dream family. iii. What have you received from your family over the years?
II. Class sharing: Family Album  (7 minutes) Teaching materials <i>Appendix 1</i>	Aim: To recall the occasions on which they received care from their parents so as to enhance motivation to contribute to families 1. Play the PowerPoint Slides again. These scenes are from a family life story of a 15-year-old. 2. Ask students to: i. Review whether they have experienced similar occasions in their lives in which they received similar care from their parents; ii. Note down the experiences which have deeply impressed them. 3. When the slides are finished, ask students to share their reflections with classmates sitting next to them. 4. Ask a few students to share with the class their life experiences which have impressed them deeply. It may be the happiest ones or the ones which make them remember the care and love of their parents.
III. Personal reflection: What can I do for my family?  (10 minutes) Teaching materials <i>Appendix 2</i> <i>Appendix 3</i>	Aim: To explore the roles students may play at home and contributions they can make to their families 1. Hand out the Worksheets (<i>Appendix 3</i>) and briefly introduce the content (Play the PowerPoint slides where needed). 2. The pictures are of a building where 8 families live. Ask students to circle the household problems in the family scene with which they think they CAN help. 3. Among the above chosen problems, ask students to use another color to indicate the ones which they HAVE experienced making a contribution in real life. 4. Invite students to think and share about: i. Among those household problems where students think they CAN help, how many of them HAVE actually given a helping hand? ii. Did they circle all objects? Did anyone circle the characters instead? Did anyone suggest that providing care and concern is also a way of contribution to the family?

Activity	Procedures
IV. Conclusion (3 minutes)	1. The family has taken care of us a great deal in a variety of ways since we were born (or even before we were born). 2. Think about what we can contribute, either tangible or intangible, as a member of the family.
V. Self-reflection (5 minutes) Teaching materials <i>Growth puzzle</i>	1. Distribute the Growth Puzzle and engage students in self-reflection. 2. Praise students for their participation during the lesson.

Teaching Tips

1. “Family album”	• If time allows, ask students to bring a memorable family photo and share it with the whole class or the classmates sitting next to them in this session. • Instruct students to share why this photo is important to them. • Some students come from families of special backgrounds in that they have no living father or mother or students do not live with them. Special backgrounds include single-parent families as a result of divorce, separation, death, extended work overseas by one of the parents, separation due to immigration restrictions, etc. Instructors should pay special attention to the emotional response of such students and guide them to think about the care and love their father, mother or guardians have given them. • Invite students who are rather silent in class or have been labeled as “problematic” to share their experiences. This provides students an opportunity to express themselves and their stories are likely to be very moving and sensitive. Should there be negative or highly emotional responses, instructors should listen to their concerns patiently and ask students nearby to comfort them. This helps establish a mutually supportive and caring learning environment. • It was found in the trial-run that students who come from families of special backgrounds can also achieve the intended learning targets. Many of them can even vividly recall childhood experiences.
2. “What can I do for my family?”	• Students who are non-Chinese may think that the setting of this part may not apply to their culture and living environment. Instructors can raise questions like: “Do you notice the differences between your family and your classmates who are from different cultural backgrounds?” or “Have you ever noticed what local families in Hong Kong are like, compared to yours?” Instructors can then lead them to see that building up your family without cultural limitation. • Students can put signs (e.g., square) or ticks to indicate their ideas, should they have no pens of different colors. • Most of the time, students tend to focus only on the objects. Instructors can, therefore, suggest they pay more attention to the characters. This not only encourages them to pay more attention to individual family members, but also establishes a linkage between “people” (family members) and “happenings” (housework), so that students may realize the hardship of their family members and not just focus on the latter. • Ask students to notice the difference between what they “can” do and what they “have already” done. The greater the difference, the more students can potentially contribute to their families. • If students are more mature, instructors can further investigate how one can help the characters, including: (i) tangible tasks such as helping mother / father to prepare the meal, teaching younger brothers / sisters to do homework, helping father by turning off the radio, studying hard so that parents do not have to worry about them, etc.; (ii) intangible tasks such as caring about father’s work, asking if you can offer any help to mother, etc. • For students who have experienced major family difficulties (e.g., one of the family members is chronically ill or died suddenly), they may think that there is nothing they can contribute. In this case, instructors should take care of their emotional response and at the same time, remind students that although there is little that they can do, their intention to help is already a kind of support to their families. Instructors can encourage them to face and overcome difficulties together with the family. • Share some of their memorable family happenings with the class (e.g., the most memorable experience at home and what s/he has done for the family) so as to build a closer relationship with students and to serve as a role model.

Supplementary Activity (Optional)

Activity	Content	Recommendations
I’d love to contribute	Aim: To make contribution to the family in order to improve relationships with families Ask students to act out what they think “CAN” contribute, but “HAVEN’T” contributed to the families as indicated in “What Can I Do for My Family?” (Appendix 3). Ask them to report to the class a week later on issues such as feelings, response from family members to their contribution, or whether there is any improvement of the relationship between them and their families.	Ask students how their family members feel after they have made such contributions. Share the results with the class.

Implementation Plan (30 Minutes)

Primary Activity

Secondary Activity

Activity	Procedures	Teaching Materials
I. Warm-up Activity (5 Minutes)	1. Ask students, "What is your parents' tone of voice when they usually talk to you?" 2. Log in to Interactive Learning Platform (ILP) and let students vote. 3. Students vote "the most frequently used tone by their parents" and "the one they prefer their parents to use" based on different scenarios (<i>Appendix 1</i>). 4. Present the results after the vote. 5. Summarize and conclude: The tone used by parents talking to their children may be different from the one children expect, and sometimes parents' tone may make children feel bad and damage the relationship between parents and children. Today we will try to discuss how to communicate with parents.	Appendix 1 Interactive Learning Platform

Activity	Procedures	Teaching Materials
II. Group Discussion “Parents’ Message”  (9 Minutes)	Aim: To analyze parents’ messages from person- oriented and task- oriented points of view 1. Divide the class into 8 groups and distribute the Worksheets (<i>Appendix 2</i>). 2. Play the video “Parents’ Messages” (<i>Appendix 3</i>). There are 7 scenarios about messages often expressed by parents (<i>Appendix 4</i>). 3. The groups should determine and judge the scenarios one by one and put signs on the appropriate parts of the Worksheets: i. Ratings are given to “people-oriented”: Concern/Apathy (1 refers to the lowest, 10 the highest); ii. Ratings are given to “task-oriented”: Strictness/ Leniency (1 refers to the lowest, 10 the highest); Identify whether the message is an “order,” a “request,” a “suggestion” or a “neglect” by checking the ratings against the graph. 4. Ask the groups to report to the class. 5. Summarize and conclude: i. Most parents care deeply for their children and consider their well-being; ii. Depending on the situation, parents will express messages in different ways. iii. How can children respond to their parents?	Appendix 2 Appendix 3 Appendix 4
III. Students’ Polling “My” Voice  (9 Minutes)	Aim: To learn proper response to parents’ messages to establish a good relationship with the parents 1. Ask students, “We just discussed the tone used by your parents, what kind of tone will you use when you respond to your parents?” 2. Log in to Interactive Learning Platform (ILP) and let students vote. 3. Students vote “the most frequently used tone by themselves” and “the proper one should be used by them” based on different scenarios (<i>Appendix 5</i>). 4. Present the results after the vote. 5. Depending on the situation, the instructor himself/herself or invites some students to read those statements using the tone of “order,” a “request” or a “neglect” for different scenarios: i. Invite students to identify the tone used by the students. ii. Ask students, “If you were parents, how would you feel when you hear your children’s response in such a tone?” and invite students to share their discussion. 6. Invite students to use the tone of “suggestion” to act out the scenarios. 7. Ask students, “If you were parents, how would you feel when you heard your children’s response in the tone of ‘suggestion’?” 8. Encourage students to use “I-message” with “suggestion” tone as a proper response to their parents: i. Feelings; and ii. Views about an issue. 9. Explain to students, “Appropriate response allows students to present their feelings and views calmly and promotes a harmonious atmosphere for effective communication.”	Appendix 5 Interactive Learning Platform
IV. Conclusion (2 Minutes)	1. “Quarreling” and “keeping silent” are two common responses to our parents’ messages. Both responses hide our real thoughts, which prevents communication. We should reveal and share more of our real feelings and thoughts with our parents. 2. “Filial piety” is the core virtue in the Chinese culture and students can practice this by showing sympathy with their parents in responding to their parents’ messages.	
V. Self-reflection (5 Minutes)	1. Distribute the worksheet of Reflective Questions and engage students in self-reflection. 2. Praise students for their participation during the lesson.	Reflective Questions

Teaching Tips

1. Warm-up Activity	Instructors may share their personal experiences to arouse students' interest and increase their involvement.															
2. "Parents' Messages"	- If time allows and if students are mature enough, instructors can direct students to think about the general meanings behind the following types of expressions:<table><tr><td>Type of expression</td><td>Parent-child relationship</td><td>The message suggests ...</td></tr><tr><td>Order</td><td>Parents have a higher status than the children.</td><td>A sense of urgency and seriousness. Children keep ignoring parents' messages.</td></tr><tr><td>Request</td><td>Parents and children have a relatively equal status.</td><td>The situation is not that urgent and the children are willing to follow parents' words.</td></tr><tr><td>Suggestion</td><td>Parents and children share the same status and they get along with each other very well.</td><td>The situation is not urgent at all and there is good communication between the parents and the children.</td></tr><tr><td>Neglect</td><td>Parents and children have an alienating relationship.</td><td>A lack of communication and the parents and children are emotionally distant.</td></tr></table> - Ask students to think what they should do to promote parent-child communication that promotes the "Suggestion" expression in their communication. - Some students may say that their parents "neglect" them most of the time. In this case, instructors should pay special attention to such students and find out whether their family background may have a negative effect on their personal and emotional development. Also ask students to think about what they can do to improve their relationship with their parents. Instructors should look for other support systems where needed, e.g., seeking help from social workers or counselors. - Students who are most often neglected may try to draw attention by engaging in inappropriate or unusual behaviors (e.g., shop-lifting, being rebellious, bullying, etc.). Instructors should pay special attention to such students. Forward the case to social workers or counselors where needed.	Type of expression	Parent-child relationship	The message suggests ...	Order	Parents have a higher status than the children.	A sense of urgency and seriousness. Children keep ignoring parents' messages.	Request	Parents and children have a relatively equal status.	The situation is not that urgent and the children are willing to follow parents' words.	Suggestion	Parents and children share the same status and they get along with each other very well.	The situation is not urgent at all and there is good communication between the parents and the children.	Neglect	Parents and children have an alienating relationship.	A lack of communication and the parents and children are emotionally distant.
Type of expression	Parent-child relationship	The message suggests ...														
Order	Parents have a higher status than the children.	A sense of urgency and seriousness. Children keep ignoring parents' messages.														
Request	Parents and children have a relatively equal status.	The situation is not that urgent and the children are willing to follow parents' words.														
Suggestion	Parents and children share the same status and they get along with each other very well.	The situation is not urgent at all and there is good communication between the parents and the children.														
Neglect	Parents and children have an alienating relationship.	A lack of communication and the parents and children are emotionally distant.														
3. "I-message"	- Instructors can use some of the statements shown in <i>Appendix 5</i> for students' practice; the number of statements used for voice play depends on the class situation. - When instructors teach students to apply the "suggestion" tone to express their personal feelings, ask students to pay attention to the following principles and strategies: - Use active listening and respond slowly in a calm manner, and do not reply in a judgmental way or in a way that leads us into confrontation. - Use appropriate wordings and express your ideas clearly. - If parents ignore you or show no response, try telling them more about your feelings or show them that you are willing to discuss with them to find out ways to solve the problem. - Instructors can highlight that the "suggestion" tone can also be used when facing other people such as teachers and friends - Apart from the examples given in <i>Appendix 5</i>, instructors may also make use of statements appeared in "Warm-up Activity" (<i>Appendix 1</i>) to reinforce students' master of "I-message." - Should instructors wish to engage every student, a further exercise involving students sitting next to each other can be added. Work in pairs, one of them takes on the role of the father / mother, the other being the child and practice responding to parents by using "I-message."															
4. Self-reflection	Use the reflective questions in the Worksheet and in the PPT as appropriate.															

Supplementary Activity

Activity	Content	Recommendations
Thanks-Giving Day	Aim: To express gratitude to parents Ask students to form groups and work on finding ways to express their gratitude to their parents	Organizing a "Thanks-Giving Day" on weekends and invite parents to school. Then ask students to present their gratitude to their parents. Expressions of gratitude can be through to their parents. Expressions of through poetry, songs, pictures, and so on.

A 3.1. Reference Materials for Instructors: Online Polling Content

	Scenarios
(1)	When parents know you are going out, they will: 1) Neglect — “Oh.....Going out again.” 2) Order — “Don’t hang around all day!” 3) Request — “You should stay home.” 4) Suggestion — “Could you stay home? We have not seen you much here. ”
(2)	When parents see you are phubbing, they will: 1) Neglect — “Oh..... Phubbing again. ” 2) Order — “Put down your phone! Do more revisions! ” 3) Request — “Can you put down your phone, please?” 4) Suggestion — “How about putting your phone down, always looking at a bright screen is not good for your eyes.”
(3)	When parents see you are sleeping on bed, they will: 1) Neglect — “Oh.....Still in bed. ” 2) Order — “Wake up, NOW!” 3) Request — “Can you find something to do and not lie on the bed all day?” 4) Suggestion — “It is better to sleep at night. Otherwise, you may be unable to sleep tonight. ”
(4)	When parents think that you are bone idle, they will: 1) Neglect — “Oh.....You are lazy bone. ” 2) Order — “Go to tidy your stuff up, NOW!” 3) Request — “Do something else. I don’t want to see you sitting here.” 4) Suggestion — “Let’s have a walk. It would be better than sitting here. ”
(5)	When parents find you playing games all the time, they will: 1) Neglect — “Gaming again. ” 2) Order — “Turn off the game NOW!” 3) Request — “You should spend less time on playing the game.” 4) Suggestion — “You have played the game for a long time, how about giving your eyes a break now?”
(6)	When you respond to your parents’ blaming on you, your parents will: 1) Neglect — “I don’t care what you said. ” 2) Order — “Shut up!” 3) Request — “You should not talk back.” 4) Suggestion — “Let us know what we blamed you wrongly.”
(7)	During the final exam, your parents notice that you focus on something else rather than doing revision. They will: 1) Neglect — “Oh, you don’t need to revise. ” 2) Order — “Go over your lessons NOW!” 3) Request — “You are still sitting your exams, do your revision, please.” 4) Suggestion — “It would be great if you revise before doing something else.”
(8)	Parents want you to help do some housework, but you are phubbing. They will: 1) Neglect — “Phubbing again.” 2) Order — “Come over and help NOW!” 3) Request — “You should help do some housework in your free time.” 4) Suggestion — “Could you help me wash the dishes? You can play the game after that.”

	Scenarios
(1)	When parents said, “What time is it now? Still playing video games? You have school tomorrow morning! Go to bed now!,” you will : Neglect — “I don’t care about that.” and keep playing the game. Order — “Stop annoying me!” Request — “Let me complete this task first.” Suggestion — “I don’t want to waste my effort on this task” (Feeling) “Please give me 10 more minutes and I will go to bed, even I cannot complete it in the end.” (Views about the issue)
(2)	When parents said, “ I’m busy cooking and have run out of cooking oil...can you buy a new bottle for me?,” you will: Neglect — “Don’t bother me.” Order — “You do it by yourself!” Request — “You can do it after finishing the dishes you are cooking.” Suggestion — “I am doing my assignment.” (Feeling) “Give me five minutes. I will buy it after completing my assignment.” (Views about the issue)

	Scenarios
(3)	When parents said, "Don't bother me!" you will: Neglect — "I don't bother anymore." Order — "Fine! Remember what you said." Request — "Let me say it now." Suggestion — "I know you are troubled by something else, but I have something to discuss with you." (Feeling) "Is it okay if we discuss five minutes later?" (Views about the issue)
(4)	When parents said, "You spent less time playing video games and got better grades in last semester. I think we do the same this semester. Try to spend less time playing video games, shall we?," you will: Neglect — "Don't bother me!" Order — "Shut up!" Request — "Let me complete the game first." Suggestion — "I feel much more stressed in this exam and have to relax my mind." (Feeling) "Could you let me play game for half an hour after every two-hour revision?" (Views about the issue)
(5)	When parents said, "How many times do I need to repeat? We are going to have dinner at Grandma's place this Saturday," you will: Neglect — "I didn't hear what you said." Order — "Shut up!" Request — "I don't want to go to grandma's home." Suggestion — "I have promised to attend a gathering on that day and I am not sure what time it will end." (Feeling) "Perhaps I will have dinner with grandmother later." (Views about the issue)
(6)	When parents said, "We'll have an early dinner tonight. You should come back before 7:00 p.m." you will: Neglect — "I don't know." Order — "You can have dinner first!" Request — "Don't wait for me and do it yourselves." Suggestion — "I am not sure when I will finish my work." (Feeling) "I will call you if I cannot come back on time, and you can start first." (Views about the issue)

REFLECTIVE QUESTIONS

Name:

Class:

Date:

1. Are you satisfied with your communication with your parents now? Why?

2. How can you improve your communication with your parents effectively? Please elaborate with examples.

3. Please write down the advantages of using "I-message" as a reply.

ABSTRACT

A survey of the literature showed that most research studies in children, adolescents and families have been conducted in Western contexts, which may not be applicable to non-Western contexts. Hence, research on children, adolescents and families in non-Western contexts is particularly important and we therefore need to enrich human development and family research in the Chinese context. In this book, we included 16 chapters to demonstrate the advances in Chinese children, adolescents, and family

research. And it is our sincere hope that through this book, we can attempt to conduct more empirical studies that can help to promote the research atmosphere and enrich the knowledge of Chinese children, adolescent, and family research in a larger context.

INTRODUCTION

A survey of the literature showed that most research studies in children, adolescents and families have been conducted in Western contexts. One major limitation is that the related theories and findings may not be applicable to non-Western contexts. Hence, research on children, adolescents and families in non-Western contexts is particularly important. As roughly one-fifth of the world's population are Chinese, the development of research on human development and families in the Chinese context is very important. Although more Chinese research studies have been conducted in the past decades, most of the studies were based on Western theories and tools. Due to cultural differences, it is argued that researchers and practitioners should develop their own theories, programs and measurements [1-3].

There are several areas that require more Chinese research. The first area is the prevention intervention research. For example, by adopting fifteen positive youth development constructs from the West, the first local positive youth development program ("Project P.A.T.H.S.") has been developed for Hong Kong junior secondary students since 2005. Since the implementation, the research team employed multiple evaluation strategies to ensure the quality of the program implementation, such as subjective and outcome evaluation, process evaluation, and focus group and individual interviews. Also, based on the results of the evaluation, the program materials have been updated and revamped based on the results of the evaluations during the 15-year program [4-5].

MAINLAND CHINA

Based on the positive feedback and effectiveness of the Project P.A.T.H.S. in Hong Kong, the program has been introduced into mainland China ("Tin Ka Ping P.A.T.H.S. Project") since 2011 for more than 28 mainland China cities. However, due to the cultural differences between Hong Kong and mainland China, there is a need to have ongoing feedback from different stakeholders. Normally speaking, the teaching style of Hong Kong teachers is more interactive when compared with the style of mainland Chinese teachers. For positive youth development programs, like Project P.A.T.H.S., interaction and students' participation are key factors for promoting students' reflection and learning. Therefore, apart from providing trainings for teachers and program implementers, feedback from both participants and program implementers can not only help researchers to have a full picture of the program effectiveness, but also facilitate program implementers' reflection on their teaching performance and improvement. This example proved that ongoing evaluations and researches are needed for adopted programs for better program effectiveness. In this book, we included some related papers on the Tin Ka Ping Project in China.

EVALUATION

Second, we need more research on the evaluation of holistic adolescent development programs. In order to have a comprehensive picture of the program's effectiveness, it is suggested to collect feedback from both participants and different stakeholders, including program implementers. Besides collecting participants' feedback, it is also important to collect feedback from the program implementers for several reasons: (i) program implementers are more experienced than participants, and they can provide more "accurate" views towards the programs; (ii) it can facilitate reflective practice and to enhance the quality of the programs; (iii) it can provide a better understanding about the implementation process across different settings/schools, especially for those programs which are implemented in different schools; (iv) according to the principle of triangulation, collecting data from different sources can help researchers to generate the same picture and further examine if there are different views among participants and stakeholders. In this book, we included some papers on evaluation based on different evaluation strategies.

Beside intervention research, it is also important to understand adolescent development. As there are few studies on adolescent materialism and egocentrism, there is a need to conduct more studies in this area. Furthermore, there is a need to conduct more longitudinal studies. Although there is an increase of longitudinal studies in adolescents' development, longitudinal studies about late adolescents' well-being (e.g., university students) are still lacking in number, especially in the Chinese context [6]. University life should be regarded as an important transition period from adolescence to adulthood. However, there is a myth in the Chinese society that university students need less support and concern as they are "old" enough to face different challenges. In this book, several papers on adolescent materialism and egocentrism are included. Also, some papers on the development of university students are covered.

FAMILY RESEARCH

Finally, several points should be noted when conducting family research: (i) cultural differences should be taken into consideration, (ii) there is a need to examine the differential paternal and maternal influences when examining a factor on children and adolescent; and (iii) both parents' and children' views should be included in a single study. Because of the unique historical backgrounds between the West and East, cultural differences should always be considered when studying family factors in the Chinese context. Besides, to have a complete understanding of different sides, it would be good to include both parents' and children's views in a single study.

THIS BOOK

Based on the above discussion, there is a need to enrich human development and family research in the Chinese context. In this book, we included 16 chapters to demonstrate the advances in Chinese children, adolescents, and family research. And it is our sincere hope

that through this special issue, we can attempt to conduct more empirical studies that can help to promote the research atmosphere and enrich the knowledge of Chinese children, adolescent, and family research.

ACKNOWLEDGMENT

In this book we have gathered single papers published earlier in several of Nova journals with permission relevant to the topic of the book.

Chapter 316

RELIABILITY AND VALIDITY OF THE CHINESE VERSION OF THE PSYCHO-EDUCATIONAL PROFILE (THIRD EDITION) FOR CHILDREN WITH DEVELOPMENTAL PROBLEMS

Daniel T. L. Shek*, PhD, FHKPS, BBS, JP and Lu Yu, PhD

Department of Applied Social Sciences, The Hong Kong Polytechnic University,
Hung Hom, Hong Kong, PR China

ABSTRACT

The Psycho-Educational Profile-3rd edition (PEP-3) is a popular instrument that assesses the skills and behaviors of children with autism and communicative disabilities, while its application in Chinese population has not been systematically examined. Based on the data collected from a clinical sample of children ($N = 455$) diagnosed as having autism spectrum disorder (ASD) and other pervasive developmental disorders (PPDs) as well as a sample of healthy controls ($N = 281$) in Hong Kong, this study examined the psychometric properties of the Performance Test of the Chinese version of the PEP-3 (CPEP-3). Different types of evidence on the reliability (internal consistency, test-retest reliability and inter-rater reliability) and validity (content validity and criterion-related validity) of the test were examined. It was found that the Performance Test of CPEP-3 possessed sound psychometric properties in assessing the developmental level of Chinese children with autism spectrum disorder in Hong Kong. The translated CPEP-3 Performance Test is a reliable and valid measure for assessing Chinese children with autism.

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

INTRODUCTION

Autism spectrum disorder (ASD) refers to a group of developmental disabilities, characterized by unreciprocated interpersonal and emotional interactions, disordered language and communication, and repetitive and stereotypic behaviors [1-3]. Although earlier studies had suggested the prevalence of autism was low, the global prevalence of ASD increased tremendously in the global context in the past decades [4-8]. While children with ASD share similar symptoms, the age of onset, nature and severity of the problems are highly variable, which require different treatment approaches [9]. Hence, psychometrically sound instruments that can help professionals to objectively assess children with ASD are of great importance to ensure accurate diagnosis and appropriate educational programming [10].

According to Shriver, Allen and Mathew [11], assessment is considered as core components in treating children with ASD in terms of three aspects. First, assessment helps to obtain an accurate verification for the diagnosis and special education eligibility. Second, assessment can guide the development of appropriate interventions by providing a descriptive profile on children's development in different areas. Third, assessment enables researchers to establish baselines against which evaluation of different intervention programs could be conducted.

Among different types of assessments measuring children with ASD, the Psycho-Educational Profile-3rd edition (PEP-3) is a standardized observation tool primarily designed for planning educational program for children with ASD from 2 to 7 years of age [12]. It is the revised version of the Psycho-Educational Profile-Revised (PEP-R) which has been widely used in different parts of the world for the assessment of children with ASD in terms of their developmental skills and behaviors [13-17]. Compared with the PEP-R, there are several significant improvements in the PEP-3. First, the measured function domains have been revised by incorporating the most recent research findings, such as the social and communication aspects. Second, normative data from both a sample with autism and a typically developing sample were provided which makes it possible to compare the two groups of children on their developmental profiles. Third, a Caregiver Report, which utilizes information reported by parents and other caregivers about the child's development and behavior in daily lives, has been added to help professionals have a fuller understanding about the child. Fourth, new items and important subtests were added into the PEP-3 while obsolete items were deleted. The validity of the revised instrument has been examined in the West [18].

Specifically, the PEP-3 consists of two complementary parts. The first part is a norm-referenced performance scale (Performance Test) which measures autistic children's development in three areas: communication, motor skills, and maladaptive behaviors. The second part is a parent or caregiver reported form (Caregiver Report). Children's development and performance in communication, motor and social functioning, adaptive behaviors and thinking are rated by their caregivers based on their daily observation. As autistic children's symptoms vary across settings (such as people, places, and things the child interacts with), using both professional observers' ratings on children's performance in the laboratory and caregivers' ratings on children's daily lives helps to obtain a richer and comprehensive developmental profile of the child with reference to the strengths and weaknesses of the child in different environment. This could be very useful for professionals

to design individualized educational and behavioral intervention programs in different settings.

Based on a normative sample of 407 children with ASD and 148 children with typical development in the United States, Schopler et al. [18] reported the reliability and validity of the PEP-3 in its user manual. As far as reliability is concerned, the PEP-3 showed high reliability, with all subtests showing high internal consistency (alphas ranged from 0.84 to 0.90) and temporal stability (test-retest coefficients over a period of two weeks ranged from 0.94 to 0.99). Besides, for the inter-rater reliability for the Caregiver Report, the polychoric correlation coefficients ranged from 0.52 to 1.00. In terms of validity, consistent with the expectations, autistic children's scores on PEP-3 Performance subtests were negatively correlated with their scores on measures of symptom severity in autistic children, including the Childhood Autism Rating Scales (CARS) [19] and the Autism Behavior Checklist-Second Edition (ABC) [20]. For the Caregiver Report, positive correlation coefficients were found between the Vineland Adaptive Behavior Scales (VABS) [21] which assess parent-reported adaptive behavior of children and PEP-3. These findings provide sound support for the good psychometric properties of the PEP-3 when applied to children with ASDs in the United States.

The PEP-R has been translated into several languages and research findings supporting the psychometric properties of the translated measures have been reported [14, 15, 22]. In contrast, there are very few reports on the application of PEP-3 in countries other than the United States [23]. As Chinese people constitute roughly one-fifth of the world's population, translation of PEP-3 to Chinese and establishment of the related psychometric properties should be conducted. Actually, a Chinese version of the PEP-R (CPEP-R) was validated and used in assessing children with ASD in Hong Kong since 2005 which has largely facilitated the diagnoses and treatment of autistic children [14]. Nevertheless, very few reports have been published on the Chinese version of PEP-3 and its psychometric properties. In Taiwan, researchers translated the PEP-3 into Chinese and reported the reliability and validity of the instrument based on Taiwanese children with autism. While the preliminary findings supported the application of PEP-3 in Chinese children, the published studies were mostly based on small samples (ranged from 42 to 64 participants), which makes the generalization of the findings to other Chinese population questionable [22-24].

Against the above background, Heep Hong Society, the biggest organization in Hong Kong that provides professional training and education to children with developmental and learning problems and their families, invited a group of experts consisting of psychologists, occupational therapists, special educators, and special child-care workers to translate the PEP-3 into Chinese [25] and conduct a validation study to examine the psychometric properties of the instrument. Based on a sample of 455 children with ASD and a comparison group of 281 children with typical development, the construct validity of the Chinese version of PEP-3 (CPEP-3) was examined. It was found that older children scored higher than younger children for both groups on different subsets of CPEP-3, while no gender difference was identified within the autistic group. The results of confirmatory factor analysis further showed the three-factor theoretical model of the Performance Test fitted well. These findings provide important evidence for the construct validity of the CPEP-3 [25]. However, besides construct validity, there is a need to further understand the reliability as well as other types of validity of the CPEP-3.

As far as reliability is concerned, three types of reliability are commonly assessed for an assessment tool [26]. First, Cronbach's alphas are usually computed to examine the internal consistency of the scale to see whether the items measure something which is homogenous in nature. Second, temporal stability of the test scores (i.e., test-retest reliability) is typically examined by getting the test scores at two different time points. Finally, if the test is completed by different raters, consistency across raters is examined by inter-rater reliability.

Regarding validity, besides construct validity which was examined in the study of Shek and Yu [25], two additional forms of validity evidence were examined in the present study. First, evidence about content validity was explored, which refers to "the systematic examination of the test content to determine whether it covers a representative sample of the behavior domain to be measured" [27]. Based on the method adopted by the original author of PEP-3 [12], conventional item analyses were performed to provide evidence for content validity, including item discrimination and item difficulty analyses. Second, criterion-related validity was investigated, which was defined as the correlation between a test and an (or a series of) external criterion variable(s) taken as representative of the construct, for example, measures that have previously been validated assessing presumably related constructs [27]. In this study, it was hypothesized that the Performance Test of CPEP-3 should correlate well with previously validated tests that measure developmental skills and behavioral symptoms in children with autistic disorders.

The primary purpose of this paper is to report the reliability and validity of the Performance Test of the Chinese version of PEP-3 (CPEP-3) based on further data collected from the same samples of children as reported in Shek and Yu's [25] paper. Psychometric properties of the Caregiver Report will be presented elsewhere [28]. Specifically, the current study attempted to assess the reliability (internal consistency, test-retest reliability and inter-rater reliability) and validity (content validity and criterion-related validity) of the CPEP-3 Performance Test as a measure to estimate the developmental level among children with ASD in Hong Kong.

OUR STUDY

Prior to the study, approval to conduct the study (including ethics approval) was obtained from the Executive Committee of Heep Hong Society. The primary caregivers of the participated children have given their written informed consents to the research team. Participants were ensured that the data collected in the study would be kept confidential.

Participants

As described in Shek and Yu's [25] paper, 455 children who were diagnosed as having autism or other pervasive developmental disorders (PDDs) in 25 service units in Heep Hong Society including special child care centers, early education and training centers, and parent resource center were recruited to participate in the study. Another sample of 281 children without developmental problems was selected as the "healthy control" from 13 local kindergartens matched for age with the autistic sample for comparison. The diagnoses of the

autistic sample were made based on ICD-10/DSM-IV by consultant psychiatrists and endorsed by a multidisciplinary team consisting of clinical psychologists, special educators, and other helping professionals. Several subgroups of participants were randomly selected for the analyses of test-retest reliability, inter-rater reliability, and criterion-prediction validity.

Table 1. Demographic characteristic of the samples

Age group	2	3	4	5	6	7	
Age range in years	2.0-2.9	3.0-3.9	4.0-4.9	5.0-5.9	6.0-6.9	7.0-7.9	Total
Sample with autism							
No. of participants	32	79	140	161	37	6	455
Percentage	7.0%	17.4%	30.8%	35.4%	8.1%	1.3%	100%
No. of girls	6	11	22	22	5	0	66
No. of boys	26	68	118	139	32	6	389
Typically developing sample							
No. of participants	67	60	60	62	30	2	281
Percentage	23.8%	21.4%	21.4%	22.1%	10.7%	0.7%	100%
No. of girls	34	37	36	30	14	1	152
No. of boys	33	23	24	32	16	1	129

Participants' age ranges from 2.0 to 7.9 years. The characteristics of the two samples in terms of age and gender can be seen in Table 1. For the autistic sample, the ratio of boys to girls is 6:1, which is consistent with the reflecting the fact that boys have a higher risk of autistic disorders than girls. While this figure is higher than the related ratio (4:1); in the sample reported in Schopler et al. [12], it is highly similar to the findings of a large epidemiological study of autistic spectrum disorder in which the male to female ratio was found to be 6.58:1 in Hong Kong children [8]. Scores of the sample with ASD and the typically developing sample were compared as an indication of criterion-related validity.

Procedures

The translation of the CPEP-3 followed standard procedure in questionnaire adaptation, of which the details were reported in Shek and Yu's [25] paper. A group of professionals including speech therapists, occupational therapists, educational psychologists, and preschool teachers administered the tests and rated the participants' performance. All of the raters had experience working with and testing young children. Before the formal launching of the validation study, training sessions were conducted so that the raters worked together to clarify and get familiar with general testing, scoring and interpreting procedures of the CPEP-3 to ensure consistency in the test administration.

To investigate whether the participants' test performance is consistent over time, test-retest reliability was examined on a subsample of 42 children with autism. Six girls and 36 boys between 2.3 and 5.9 years of age were tested twice over a period of time that ranged from 6 weeks to 3 months. The variation of the interval was due to difficulties in the arrangement involved.

Besides, inter-rater reliability was conducted on a subsample of 46 children randomly selected from the autistic group with age ranging from 2 to 5 years (5 girls and 41 boys) to

understand whether the test would be affected by subjective ratings of different raters. Each subject was administered the CPEP-3 Performance Test independently by one administrator and two co-raters as observers. The administrator-co-raters grouping was randomly assigned by a research assistant who was blind to the characteristics of the subjects. In order to keep neutrality throughout the process, testing conditions were similar for all the children and the researchers involved in the case would rate the child's performance independently and handed the protocols to the research assistant directly for data entry.

To test the criterion-related validity of CPEP-3 Performance Test, two established measures related to developmental problems were administered on a subsample of 64 children with autism (56 boys and 8 girls) aged 2 to 6 years. The two measures included the Merrill-Palmer Revised Scales of Development (MPR) [29] and the Childhood Autism Rating Scale (CARS) [18]. Both measures were administered by the raters and the participants were randomly assigned to the researchers. The correlations between the criterion measures and CPEP-3 Performance Test would serve as an index of criterion-related validity.

Instruments

The Chinese Version of Psycho-Educational Profile—3rd Edition (CPEP-3)

The PEP-3 has two major parts: Performance Test and Caregiver Report. The 172-item Performance Test is composed of 10 subtests. Three subtests measure communication ability including Cognitive Verbal/Preverbal (34 items), Expressive Language (25 items), and Receptive Language (19 items). Another three subtests measure motor ability: Fine Motor (20 items), Gross Motor (15 items), and Visual-Motor Imitation (10 items). These six subtests focus on the child's developmental level. The rest four subtests measure maladaptive behaviors, including Affective Expression (11 items), Social Reciprocity (12 items), Characteristic Motor Behaviors (15 items), and Characteristic Verbal Behaviors (11 items). The Caregiver Report consists of 38 items which are combined into three subtests: Problem Behavior (10 items), Personal Self-Care (13 items), and Adaptive Behavior (15 items). The current study focuses on examining the Performance section.

Authorized by the PEP-3 developers, Heep Hong Society organized a working group comprising clinical, developmental and educational psychologists to translate the PEP-3 items into Chinese. The translated draft was then reviewed and modified by the group after discussion. Compared with the English version of PEP-3, changes in the CPEP-3 were made in the areas of language and use of stimuli. Adaptation and modifications were conducted taking into account the cultural and language factors. Chinese words were used to replace the English ones in the items for letter matching, naming and sorting, and a few more culturally suitable pictures were used to replace the original ones. The scoring of items has been quantified as 0, 1, and 2, with "Pass" = 2, "Emerge" = 1, and "Fail" = 0.

To assess the convergent validity of the CPEP-3, the following measures were employed:

Merrill-Palmer Revised Scales of Development (MPR)

The MPR is an individually-administered, norm-referenced measure of children's development in cognitive, language, motor, self-help, and social-emotional domains [29]. It is characterized by a wide range of visual-motor tasks and a few verbal items. This instrument

has been widely used by practitioners in assessing the cognitive functioning of pre-school children with language and cognitive delays, with high scores suggesting high cognitive functioning. There are seven subscales in the MPR: development, cognitive, fine motor, infant language/receptive language, infant memory/memory, speed, and visual motor, measuring different areas of cognitive functioning. It was hypothesized that positive correlation would be found between MPR scores and CPEP-3 Performance subtest scores.

Childhood Autism Rating Scale (CARS)

The CARS is a behavioral rating scale developed by the TEACCH Division [18]. The CARS consists of ratings in 15 different areas of functioning significant for autism: Relating to People, Imitation, Emotional Response, Body Use, Object Use, Adaptation to Change, Visual Response, Listening Response, Taste, Smell, and Touch Response and Use, Fear or Nervousness, Verbal Communication, Nonverbal Communication, Activity Level, Level and Consistency of Intellectual Response and General Impressions. Children's behaviors were observed and rated on a 7-point scale (4 anchor points and 3 half steps) with clear behavioral anchors. High scores on the CARS are considered more maladaptive. Both total score and subscale scores of the CARS were used in the current validity test. It is expected that negative correlation would be found between the CARS and the CPEP-3. On a sample of Hong Kong children with autism, Shek et al. [16] reported a significant correlation coefficient of 0.70 between the Behavioral Scale of CPEP-R and the total score of CARS.

Table 2. Cronbach's alpha coefficients and mean inter-item correlation coefficients for the CPEP-3 performance subtests and composites

Age Group	2	3	4	5	6	7	Average	Mean inter-item correlation coefficients	No. of items
Performance Subtests

Motor	0.93	0.96	0.95	0.96	0.87	0.82	0.96	0.36	45
Maladaptive Behaviors	0.96	0.97	0.97	0.97	0.93	0.89	0.97	0.40	49

Note. CVP = cognitive verbal/preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

Data Analyses

Preliminary data screening was performed to verify the suitability of the current data for parametric analyses. The psychometric properties of CPEP-3 were examined at both the subtests and composite levels. First, three types of reliability tests were conducted to examine the consistency of CPEP-3 subtests and composites on the current samples of Hong Kong children. These included internal consistency, test-retest reliability, and inter-rater reliability. Second, conventional item analyses including both item difficulty and item discrimination were performed to provide evidence for the content validity. Third, convergent validity of CPEP-3 was examined by testing the correlation coefficients between CPEP-3 and the two criterion scales, MPR and CARS, which measure similar domains of development as measured by CPEP-3.

FINDINGS

Internal consistency was first examined for the subtests and composites of CPEP-3 Performance Test using the total autistic sample and the subsamples at six age intervals separately. The Cronbach’s alpha coefficients and mean inter-item correlation coefficients are reported in Table 2. For the whole autistic sample, the Cronbach’s alpha coefficients ranged from 0.89 to 0.97 for the Performance subtests, and ranged from 0.96 to 0.99 for the composites. The values of the mean inter-item correlation coefficients were also acceptable (equaled to or exceeded 0.32 and 0.36 for the Performance subtests and the composites, respectively).

Table 3. Test-retest reliability for the CPEP-3 performance subtests

PEP-3 Values	First Testing		Second Testing		r
	M	SD	M	SD	
Performance Subtests					
CVP	38.26	16.89	40.00	17.36	.98
EL	13.07	11.26	13.79	12.30	.99
RL	18.00	11.43	18.76	11.43	.97
FM	31.19	6.46	31.62	6.66	.96
GM	25.38	5.26	26.29	5.20	.92
VMI	12.62	4.70	13.26	5.11	.93
AE	13.43	3.91	14.05	3.40	.84
SR	13.14	4.27	13.74	3.93	.92
CMB	20.71	6.91	21.40	6.69	.95
CVB	7.86	5.99	8.38	5.97	.96

Note. CVP = cognitive verbal/preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

To investigate the temporal stability of the assessment tools, test-retest reliability was examined on a subsample of 42 randomly selected children with autism. The temporal stability of the CPEP-3 was tested on 6 girls and 36 boys between 2.3 and 5.9 years of age over a period of time ranged from 6 weeks to 3 months. Means and standard deviations of participants’ scores at the two time points are presented in Table 3. Correlation coefficients

between test and retest raw scores for each subtest were computed. Results showed that test-retest correlation coefficients were all above 0.82, indicating a good time sampling reliability of the Chinese version of PEP-3.

Table 4. Polychoric correlation coefficients for CPEP-3 performance subtest items

Performance Subtests	Min	Max	Mean	Median
CVP	0.26	1.00	0.78	0.87
EL	0.41	1.00	0.77	0.81
RL	0.47	0.93	0.71	0.77
FM	0.23	0.96	0.60	0.76
GM	0.14	0.95	0.58	0.62
VMI	0.63	0.91	0.78	0.79
AE	0.11	0.59	0.34	0.34
SR	0.25	0.75	0.46	0.41
CMB	0.47	0.61	0.52	0.48
CVB	0.19	0.71	0.48	0.52

Note. CVP = cognitive verbal/preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

The reliability between raters was also assessed to understand whether the test would be affected by subjective ratings of different raters. The inter-rater reliability was based on a randomly selected subsample of 46 children with age ranging from 2 to 5 years (5 girls and 41 boys). Two experienced raters evaluated the 46 children independently using the 10 Performance subtests of CPEP-3. Polychoric correlation coefficients for each pair of items rated by different examiners were calculated as an indicator of inter-rater reliability [30]. Descriptive statistics about the correlation coefficients for ten Performance subtests are summarized in Table 4. Because polychoric correlation requires bivariate normality of data, skewness of items was computed initially. Results revealed that 61 out of 344 items skewed greater than the absolute value of 2. Among these items, 12 items (items 42, 120, 155, 3, 70, 97, 56, 62, 69, 135, 137, and 138) yielded polychoric correlation coefficients that appeared to be significantly biased under the condition of bivariate normality. These correlation coefficients were then excluded in the calculation of the range, mean and median of the polychoric correlation coefficients for their corresponding subtests. As can be seen in Table 4, the mean and median polychoric correlation coefficient for each subtest ranged from 0.34 to 0.78 and from 0.34 to 0.87, respectively. According to Hopkin and Stanley [31], these values can be regarded as evidence showing good inter-rater reliability.

Validity of CPEP-3 Performance Test

Regarding the content validity, the rationales underlying the selection of subtest items were established by the test developers in the United States. In fact, an earlier version of PEP-R in Chinese was used in Hong Kong to assess children with autism [14, 32] and showed sufficient clinical validity [33]. The PEP-3 is a modified version of the original PEP-R based on the experience of using this instrument in the United States for more than 20 years. After being translated into Chinese, all test materials and procedures of CPEP-3 were scrutinized by

a steering group consisting of local experts including psychologists, occupational therapists and special teachers in Hong Kong. They generally held the expert view that items of the CPEP-3 are representative and highly relevant to the domains assessed.

Besides content validity supported by expert views, tests of item discrimination and item difficulty were conducted. Item discrimination refers to the extent to which success on an item corresponds to success on the whole test, which can be indexed by the correlation between a specific item and the other items of the questionnaire. Consistent with the method used by the original scale developers, item-total score correlation coefficients were calculated on the current autistic samples of children (age 2 through age 7) to represent for the item discrimination of the CPEP-3 items.

Table 5 shows the median item discrimination coefficients for each subtest of CPEP-3. Using the criterion that discrimination indexes of 0.35 or higher are acceptable [34-35], most items can be regarded as having good item-discrimination ability on both the whole sample and different age groups. For children aged at 7 years or older, item-discrimination indices for several subtests (RL, GM, VMI, CMB, and PSC) are either uninterpretable or less than 0.35, which may be due to the limited number of participants in this age group ($N = 6$).

Table 5. Item discrimination for the CPEP-3 performance subtests

Performance subtests	2	3	4	5	6	7	Overall
CVP	0.54	0.62	0.67	0.74	0.61	0.35	0.72
EL	0.63	0.72	0.77	0.81	0.71	0.85	0.83
RL	0.64	0.81	0.75	0.80	0.65	0.22	0.80
FM	0.46	0.58	0.59	0.63	0.48	0.77	0.61
GM	0.46	0.57	0.52	0.58	0.52	-	0.59
VMI	0.60	0.67	0.61	0.66	0.42	-0.33	0.68
AE	0.60	0.59	0.67	0.71	0.21	0.91	0.66
SR	0.56	0.56	0.61	0.66	0.51	0.72	0.63
CMB	0.61	0.63	0.58	0.61	0.59	0.11	0.64
CVB	0.83	0.78	0.73	0.77	0.52	0.60	0.76

Note. CVP = cognitive verbal/preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

Table 6. Item difficulty for the CPEP-3 performance subtests

Performance Subtests	2	3	4	5	6	7
CVP	18.8%	42.4%	59.3%	69.9%	89.2%	100%
EL	3.1%	19.0%	36.4%	49.7%	75.7%	83.3%
RL	21.9%	45.6%	62.9%	73.9%	89.2%	100%
FM	48.5%	70.3%	87.2%	91.0%	96.0%	100%
GM	53.1%	75.9%	88.6%	93.8%	100%	100%
VMI	14.1%	40.5%	62.5%	67.1%	82.5%	100%
AE	53.1%	46.8%	57.9%	68.3%	73.0%	83.3%
SR	21.9%	22.8%	44.3%	48.1%	63.6%	83.3%
CMB	43.8%	51.9%	64.3%	67.7%	73.0%	100%
CVB	12.5%	20.5%	35.7%	42.2%	64.9%	66.7%

Note. CVP = cognitive verbal/preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

Item difficulty refers to the percentage of participants who can pass a given item, which helps to identify whether an item is too difficult or too easy. Anastasi and Urbina [27] suggested an average item difficulty of 50%, with a range of 15% to 85% considered acceptable. Table 6 summarizes the median item difficulty for each subscale of CPEP-3 on the autistic sample of children. For most parts of the test, test items satisfy the requirements. Results showed that as age increased, the percentage of children who passed the item also increased. These results are also consistent with the Western findings [12].

To test the criterion-related validity of CPEP-3, two well-known measures, MPR and CARS were used as criterion measures based on a subsample of 64 randomly selected autistic children. Descriptive information about the two measures and their subscales is reported in table 7. As shown in table 8, MPR subscale scores were positively correlated with the subtest scores of CPEP-3 Performance Test. All correlation coefficients were significant with values being moderate to large. This suggests high convergent validity of the Performance subtests of CPEP-3 when applied to Chinese children. For CARS, both its total score and subscale scores were used in the current validity test. As CARS measures malfunctioning in autistic children, it is expected that negative correlation would be found between the CARS and the CPEP-3 Performance subtests. As can be seen in Table 9, with a few exceptions, most correlation coefficients were significant, with the direction of the correlation coefficients consistent with the hypotheses, providing further evidence for the criterion-prediction validity of the CPEP-3. These findings were also comparable favorably with previous validation studies conducted in the United States using the CARS as one criterion measure for PEP-3 [12].

Table 7. Descriptive information on two criterion measures and their subscales

		Mean	SD	Range
MPR	Development	179.27	54.86	38.00-237.00
	Cognitive	82.20	22.22	24.00-110.00
	Fine motor	47.20	12.27	13.00-64.00
	Infant language/receptive language	49.61	21.80	0.00-71.00
	Infant memory/memory	15.95	8.78	0.00-34.00
	Speed	14.72	4.70	2.00-20.00
	Visual motor	44.84	10.42	10.00-55.00
CARS	Relating to people	2.52	0.53	1.50-4.00
	Imitation	2.16	0.82	1.00-4.00
	Emotional response	1.82	0.68	1.00-3.50
	Body use	2.08	0.54	1.00-3.50
	Object use	2.30	0.50	1.00-3.50
	Adaptation to change	2.03	0.68	1.00-3.50
	Visual response	2.23	0.74	1.00-3.50
	Listening response	2.32	0.51	1.00-3.00
	Taste, smell, and touch response and use	1.78	0.68	1.00-3.00
	Fear or nervousness	1.24	0.62	1.00-4.00
	Verbal communication	2.59	0.75	1.00-4.00
	Nonverbal communication	1.95	0.62	1.00-3.00
	Activity level	1.52	0.65	1.00-3.00
	Level and consistency of intellectual response	1.84	0.62	1.00-4.00
	General impressions	2.69	0.63	1.00-4.00
	Total score	31.05	6.03	21.50-46.00

CMB	15	0.92	0.91	0.95	0.98	0.48	-	-0.79	-0.71
CVB	11	0.95	0.93	0.96	0.95	0.52	-	-0.68	-0.65

Note. CVP = cognitive verbal / preverbal; EL = expressive language; RL = receptive language; FM = fine motor; GM = gross motor; VMI = visual-motor imitation; AE = affective expression; SR = social reciprocity; CMB = characteristic motor behaviors; CVB = characteristic verbal behaviors.

Findings of the American sample were excerpted from the PEP-3 manual (Schopler et al., 2005).

Finally, Table 10 summarizes the psychometric findings of CPEP-3 on the present sample of Chinese children and corresponding results of PEP-3 available in the PEP-3 user manual. It can be found that the psychometric properties of CPEP-3 compared favorably with those of PEP-3 reported by the test developers [12].

DISCUSSION

The aim of the present study was to further report evidence on the reliability and validity of the Performance Test of the Chinese version of Psycho-Educational Profile-3rd Edition (CPEP-3) in the assessment of developmental disorders in a Chinese context. The findings showed that the Performance Test of the CPEP-3 has good psychometric properties when applied to Chinese population, which lends support to the cross-cultural applicability and stability of the CPEP-3.

There are several unique features of this study. First, this is a pioneering scientific study of the PEP-3 on a large sample of Chinese children who are under-represented in the scientific literature on ASD. Second, consistent with the approaches adopted in Schopler et al. [12], different types of reliability and validity were examined in this study. Third, the present findings are on par or even better than those reported in the original study. Finally, the sample size of the current study was quite large considering the relatively low incidence of ASD in children.

Three different types of reliability were examined. The internal consistency of each subtest measured by Cronbach's alpha coefficient for the whole sample of children (ranging from 0.89 to 0.97) was high in this study and is comparable with the findings (Cronbach's alpha coefficients ranging from 0.90 to 0.97) reported by Schopler et al. [12] on American samples. The values of the reliability measures appeared to be higher than the previous reports on the Chinese version of PEP-R (ranging from 0.74 to 0.98) in Hong Kong context [14], which suggests that the items of CPEP-3 are more homogeneous than CPEP-R in measuring their latent constructs. For the composites, their internal consistency was also high (ranging from 0.96 to 0.99). When the Cronbach's alpha coefficients were calculated for children at different ages, it was found that all values are high, except for participants of 7 to 7.9 years of age. This may be due to the limited number of cases ($N = 6$) at this age group and the lack of variance for a few items, which make it impossible to calculate any error variance.

For test-retest reliability, a subsample of children with autism was rated twice on the Performance Test of CPEP-3 over six weeks to three months. The correlation coefficients for each subtest at the two time points ranged from 0.84 to 0.99, suggesting high test-retest reliability. In other words, the participants' scores on CPEP-3 are unlikely to be influenced by random factors in the conditions of the participants or the testing environment over time. Inter-rater reliability was assessed for 46 children with ASDs. According to the criterion suggested by Hopkin and Stanley [31] for determining the size of correlation coefficients ($0 < r < 0.1$ means very small correlation; $0.1 < r < 0.3$ means small correlation; $0.3 < r < 0.5$ means moderate correlation; $0.5 < r < 0.7$ means large correlation; and $0.7 < r < 0.9$ means very large correlation), the mean and median polychoric correlation coefficients for each Performance subtest ranged from moderate to very large. This provides support for the inter-

rater reliability of the CPEP-3 Performance subtests. The findings suggest that using the CPEP-3, different examiners rated the items in a consistent way.

Consistent with western findings, traditional item analyses on the CPEP-3 Performance Test showed that both item discrimination and item difficulty were at an acceptable range, and with age increased, the percentage of participants who passed a particular item also increased. These findings support the content validity of the instrument. The evaluation of the criterion-related validity as a measure to estimate the developmental level in comparison with two standardized developmental assessment measures (MPR and CARS) on a subsample of 64 autistic children demonstrated that CPEP-3 can be well used to effectively quantify the developmental level of children with ASDs. Significant correlations were found between CPEP-3 and the two criterion measures, MPR and CARS. These findings echo with the findings reported by Schopler et al. [12] on samples of children in the United States and provide evidence for the criterion-related validity of CPEP-3.

Overall, the above findings support that the CPEP-3 Performance Test had good reliability and validity when applied to Hong Kong samples, which compared favorably with previous findings based on American samples. The summary shown in Table 10 clearly suggests that the translated CPEP-3 Performance Test is a reliable and valid measure for assessing Chinese children with autism and its results can be regarded as consistent.

It should be noted that there are several limitations in the present study. First, the study was conducted in Hong Kong and spoken Cantonese was used as the language for the administration of the test. Therefore, the participants may not be representative of the children with autism in a broader Chinese context, particularly for Mandarin-speaking areas. Further studies must be conducted in other Chinese societies and evaluate the psychometric properties of CPEP-3 when administered in Mandarin. Second, while one significant difference between CPEP-3 and PEP-R is the addition of a Caregiver Report, which rates children's performance based on caregivers' daily observation, the present study only investigated the psychometric properties of the Performance Test. As the adaptive behaviors and symptom severities of children with ASDs vary across different environments, the Caregiver Report would provide important information on children's development in different contexts. To obtain a full picture of the development of children with ASDs in Chinese contexts, the reliability and validity of the Caregiver Report must be investigated. Third, although the group with autism and the control group were matched on participants' age in the present study, other factors that contribute to children's development were not taken into account, such as gender and IQ. Future study shall consider these factors when setting up the inclusion criterion in participants recruitment. Nevertheless, as a promising assessment tool for children with ASD, the psychometric properties of CPEP-3 need to be established before they can be used to guide the development of intervention programs. Researchers and practitioners are most interested in obtaining scores that are accurate, reliable, and can best estimate the child's true level of development. The present study clearly suggests that the Chinese version of the Psycho-Educational Profile-3rd edition (CPEP-3) Performance Test has good reliability and validity when it is used to measure the developmental level of children with autism spectrum disorders in a Chinese context. In future, more evidence on the construct validity of the Performance Test and the psychometric properties of the Caregiver Report of the CPEP-3 need to be further established.

ACKNOWLEDGMENTS

The study was conducted by Heep Hong Society in Hong Kong. We thank colleagues of Heep Hong Society for collecting the data for the validation study. The authorship of the paper is equally shared by the first author and second author. This chapter is a re-print with minor revision of an earlier published paper in the *International Public Health Journal* 2018;10(1) issue with permission.

ABSTRACT

In order to improve the health care service in poor rural western region of China, the Ministry of Health of the People's Republic of China and UNICEF had implemented "the Health Management Pilot County Project" in five provinces of western China. The purpose of this article is to evaluate the impacts of the project at provincial level. We collected data through two cross-sectional surveys in 1999, 2000, and used the analytic hierarchy process, the technique for order preference by similarity to ideal solution and linear weighting to analyze the data. The difference of the measurements between the two surveys was tested by paired-samples *t* test. All synthetic values of the five provinces in 2000 were higher than those in 1999 ($t = 6.62$, $P = 0.003$). The ranks of five provinces from highest to lowest were Xinjiang, Gansu, Qinghai, Ningxia and Guizhou. However, we also found disturbing facts that 10-20% of pregnant women had no prenatal care before child delivery. The project significantly improved the health service from shortly point of view, but there is still much to be done.

INTRODUCTION

Mainland China consists of 31 provincial-level administrative regions under the central government of China, including 22 provinces, five autonomous regions, four municipalities. In general, urban areas are more developed than the rural areas. Villages in the eastern region are generally more developed than the villages in the western region. In rural China, administrative households are nested in villages, which are grouped to form townships, a cluster of townships are governed by a county, tens or even hundreds of counties/cities become a provincial region. The rural health service system of China includes county hospitals such as the main county hospital, maternal and child healthcare hospital, Chinese medicine hospital, township hospitals and village health clinics. We called it “three-tier health service network.” The western region of China is a less developed social and economic area with multi-ethnic culture and diverse geographic conditions, since socio-economic reforms commenced in 1980s, some health service-related issues emerged in this region. For example, most village clinics in the western poor region of China lacked of basic medical facilities [1, 2]. Some village clinics have even used “Three-no” drugs (possibly fake drugs out of the official distribution channel) [3, 4], intravenous injections of antibiotics were overused and the hormone was abused commonly [3-5]. Village doctors were unwilling to provide primary health care for the villagers due to no payment [6, 7].

Figure 1. The western region of China and the UNICEF project provinces.

Maternal mortality ratio (MMR) in the western region of China was as high as 200 per 100,000 live births, which was four times the average urban MMR and two times the rural average MMR [8]. Infant mortality rates are nearly five times higher in the poorest rural counties than those in the wealthiest counties [9]. The growth and nutrition of children are in

worrying [9-15]. For children under 5 years of age, the percentages of child stunting and child underweight were 22.6% and 12.6% [15] respectively in rural areas, moreover in western region they were 24.0% and 22.1% [13].

In order to improve the health service especial health care of maternal and children in the poor rural western region of China, the Ministry of Health of the People's Republic of China (MOH) and the United Nations Children's Fund (UNICEF) implemented "the Health Management Pilot County Project" [16] in the forty poor counties of five provinces in the western region of China (Figure 1). In this article, we presented a provincial level analysis on data collected from the project. The counties level analysis was published by Bi, Lai and Yan [17].

OUR STUDY

Two cross-sectional surveys were conducted for the evaluation of the project. A stratified multistage random sampling was used to obtain subjects from each county [17]. The sample size was calculated based on the prevalence of anemia in children under the age of 36 months [17]. A 4-stage sampling design was adopted for the sample in three different strata (county, township and village) [17].

The design of the two surveys was developed by three steps [17]. The study protocol was reviewed and approved by the Human Research Ethics Committee of the Xi'an Jiaotong University College of Medicine. Ten survey teams were created for five provinces; the team's members consisted of the researchers from Xi'an Jiaotong University a prominent academic institute in west China and the staffs from local healthcare sectors. All questionnaires were filled in through face to face interviews by our professional interviewers trained by Xi'an Jiaotong University. We applied a set of quality control techniques during data collection and used double data entry and logical check procedures to input data [17], and employed EpiInfo to establish the database.

Data Analysis

The data in this study came from two surveys. First, in accordance with the objectives of project [16] and the four considerations: purpose, representative, objectivity and comparison [18-22], we selected twenty seven indicators from the questionnaires of the two surveys to evaluate synthetically the effects of the project. These indicators were classified into four aspects: health management, medical treatment condition, maternal health care and child health care [17]. Second, we calculated mean or median values for continuous variables and percentages for categorical variables for summary. Next step was the comprehensive evaluation and comparative analysis.

In the comprehensive evaluation, we used the Analytic Hierarchy Process (AHP) [17-19] to determine the weighting coefficients (W_j) of the four aspects, where j is for the four aspects, $j = 1$ to 4. Then we employed the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) [17, 20, 21] to compute the D_{ji} values of the four aspects of the difference year surveys ($y = 1999, 2000$) in five provinces ($i = 1$ to 5).

The comprehensive evaluation value was constructed as

$$E_{yi} = \sum_{j=1}^4 W_j \times D_{jyi} .$$

In comparative analysis, paired-samples *t* test was performed to compare the results of the difference of comprehensive evaluation value between two years, the Chi-square test was employed for each categorical indicator between 2000 and 1999. *P*-value < 0.05 was used as the threshold of indicating statistical significance for all tests in this study. SPSS was used for all data analysis and Microsoft Excel was used to draw figures.

FINDINGS

The household sample sizes in five provinces were from 1,083 (Qinghai, 14.7%) to 1,835 (Guizhou, 24.9%). Their household incomes were mainly from agriculture 81.2% (Guizhou) to 98.3% (Ningxia). Among the five provinces, Qinghai had the highest percentage of household drinking boiled water (97.2%) and Guizhou was reported with highest percentage (98.1%) of household using iodized salt for cooking. More detail percentages about each province on source of family income, drinking water, and salt are tabulated in Table 1. On average, mothers' illiteracy rates in each province were higher than fathers', the difference of the illiteracy rates between male and female in four provinces except Xinjiang was statistically significant by Chi-square test (*P* < 0.05). Both highest illiteracy rates were observed in Ningxia. More values and percentages about each province are presented in Table 2. The average birth weight in each province was about 3.13(kg) in Qinghai to 3.37(kg) in Guizhou; we observed that Gansu had highest children immunization record (95.4%); More information of children are presented in Table 3. Table 4 showed us that average percentage of children born at home were from 37.2% in Xinjiang to 82.7% in Qinghai, and Qinghai also had highest of percentage of family person, the relatives and the neighbor as midwives (40.1%). More than 63% of children's families chose the village health clinic for primary care except Xinjiang, there was 46.1% of children's families chose the their village health clinic and 33.9% of children's families chose the township hospital for primary care in Xinjiang (Table 5).

Table 1. General family information

Province	Sample		Source of family Incoming (%)		Drinking water (%)			Cooking salt (%)	
	n	%	Agriculture	others	Not boiled	Sometimes boiled	boiled	Iodine salt	others
Guizhou	1835	24.9	81.2	18.8	25.4	33.5	41.1	98.1	1.9
Gansu	1812	24.6	86.8	13.2	1.5	16.9	81.6	92.0	8.0
Ningxia	1137	15.4	98.3	1.7	2.1	31.8	66.1	56.6	43.4

Guizhou	69.8	11.5	7.9	1.4	0.5	8.8
Gansu	68.0	9.3	14.1	4.1	0.7	3.8
Ningxia	63.8	5.5	19.4	3.5	0.6	7.2
Qinghai	68.5	17.6	3.4	7.6	1.8	1.2
Xinjiang	46.1	10.6	33.9	2.4	0.9	5.8

The sample proportions of village health clinics in five provinces were from 16.1% to 24.3%. The average distance between villages and the township's administrative center was from 4.28(km) (Qinhai) to 7.06 km (Xinjiang). The average population size of a village in the end of 1998 was 1044.18(Xinjiang) to 1723.25 (Guizhou). The average yearly income per person in 1998 was ¥664.44 (about \$95, Qinhai) to 1432.31 (about \$205, Xinjiang). The villages in the sample were from poor regions. The average number of doctors per village health clinic was less than two and the age of the chief doctor of village health clinic was over 38 years old (38.55 to 44.78). More detail information about each province is tabulated in Table 6. We noticed from Table 7 that over 60% doctors' education level was secondary school or less, only 2.3% of doctors' education level in Xinjiang graduated from colleges or above, no doctors graduated from colleges and above in Guizhou and Gansu. 88.6% of village

doctors in Qinghai were “barefoot doctor,” the lowest percentage in Guizhou was 29.5%. The highest percentage (3.4%) of professional training at college level or above of doctors was in Xinjiang.

Comprehensive Evaluation

Using AHP, we computed the weighting coefficients of the four aspects, they were 0.311 0.440, 0.124 and 0.124, respectively. According to data of two surveys, we used the TOPSIS to calculate the *D* values of the four aspects of five provinces, we calculated the synthetic indicator of *E* via linear weighting, and the all values are listed in Table 8. The results showed that all *E* values in 2000 were higher than those in 1999. The difference of comprehensive values *E* between these two years was statistically significant ($t = 6.62$, $P = 0.003$) by paired *t* test. However, we found that not all of *D* values of the four aspects in five provinces in 2000 were higher than those in 1999; the provinces with higher *D* values in 2000 were Guizhou, Qinghai and Xingjian in health management; Gansu, Ningxia and Xingjian in medical treatment condition; all in maternal health care and in child health care.

The results of comparative analysis of the indicators of four aspects in two surveys were tabulated in the Table 9 to the Table 12. The differences of some indicators of four aspects were exhibited in the Figure 2 to Figure 5. The bars in all figures illustrated by the differences calculated from the values of indicators in 2000 minus the values in 1999. The symbols “*” in each figure denoted the differences of the indicators were statistically significant Chi-square test ($P < 0.05$).

DISCUSSION

In this article, we use a hybrid procedure of AHP, TOPSIS, linear weighting to evaluate synthetically the interventional effects of the health promotion project by provinces. One of the major findings from this study is that the *E* values of comprehensive evaluation in 2000 were significantly higher than that in 1999 in each of those five provinces (see Table 5). This

result indicated that the interventional measures of the project in the five provinces in China were effective. Furthermore, we can see the change from the differences of two-year measurement of *E*. the rank of five provinces from highest to lowest were Xinjiang, Gansu Qinghai, Ningxia and Guizhou. This not only shows us the promotion effects of the project but also revealed the quality of conducting the project. Comparing the *D* values in 1999 and 2000, we found that maternal health care and child health care in five provinces had been improved, but health management only in Guizhou, Qinghai and Xinjiang had been improved, medical treatment conditions only in Gansu, Ningxia and Xinjiang have been improved. The experiences of the project provided valuable information to help us to form governmental policies on health service promotion in poor rural western region of China. The promotion measures of the project also can be used by other provinces to find an effective health promotion approaches in China. However, our study also found that some disturbing and conflicting results by comparison of the indicators of four aspects in two surveys (see Tables 9-12 and Figures 2-5).

The figures showed us the changes of four aspects in five provinces before and after promotion, the bars over the X-axis in the figures showed the differences between these two years were positive, the promotion had improved the indicators of each province. Otherwise, the promotion had no effect. We can find clearly identify the issues of these four aspects in five provinces, and lead to a better understand the future improvement. Special attention should be paid to the indicators with negative values (below the X-axis).

Figure 2 shows, among the seven indicators of health management, Guizhou, Ningxia and Qinghai had four indicators under the X-axis, namely No.1, 2, 4 and 7, these four indicators. Gansu and Xinjiang was only one indicator, that is 1 and 7 respectively. In fact, it is not difficult to make improvement with strong leadership. From our experience, as long as we assigned the responsibility to the people with proper management, we should be able to have significant improvement for similar projects in the future.

Figure 3 explicit the five indicators of the medical conditions, Xinjiang, Qinghai, Guizhou, and Ningxia had 4, 3, 2 and 2 indicators respectively below the X-axis. A common issue in the five provinces was the lack of child weight scales. Without weight scale, village doctors cannot measure the weight of children and evaluate their growth. How to raise funds to purchase basic health care equipment is a top priority, it is a challenge for developing western five provinces.

Another issue was the disinfection and sterilization, especially Qinghai and Xinjiang. This two provinces need to pay more attention on the disinfectant of skin and apparatus. If disinfection and sterilization of medical devices do not work properly, medical treatment will lead to cross infection and spread disease, especially in the area with high incidence of hepatitis.

It should be noted that in order to increase percentage of hospital delivery, one of the measures of project was to reclaim package of delivery from the village doctors, so the percentage of having package of delivery should be decline. But Gansu is the only province with percentage increasing.

Figure 4 depicted the changes of difference of three indicators in maternal health care, only the Xinjiang had a negative difference of percentage of postnatal visit. Other indicators of 5 provinces had increase at different level. Table 11 showed there were 10-20% of pregnant women had no prenatal care before child delivery. Hospital births in 5 provinces had

increased significantly, but highest one was only 56.75% in Xinjiang. There is more work to do next for increase percentage of hospital birth.

Figure 5 described the three indicators of child health care. Although the percentages of breast-feeding had kind of decrease, we are pleased to see that they were still up to or above 94% (see Table 12). A common problem was children diarrhea in five provinces. Therefore, we should focus on the prevention of children diarrhea for further health education to reduce risk factors of diarrhea in children.

CONCLUSION

In summary, although our study has some limitations, data were collected through surveys and therefore subjected to biases in recall, There is no doubt that the comprehensive evaluation results of the projects in this study will play an active role in helping us understand the success experience of the project, and find the problems and defects in the process of project implementation. Provincial health administrative departments are the highest level of local administrative units; they played a major role in the supervision and management of the project and play a direct impact on effect of projects. This study can provide valuable reference for the five provinces to carrying out the project more effectively in future. It will also provide valuable reference for other provinces to implement similar project. Since the re-introduction of Chinese rural health care system at the village level in 1985, many progresses have been achieved. A recent review on the development of village doctors in China is given in [22] with an emphasize on health care finance.

ACKNOWLEDGMENTS

We sincerely thank the Ministry of Health of the People's Republic of China (MOH) and the United Nations Children's Fund (UNICEF) for their great supports and local health bureaus for their strong cooperation. We are very grateful to members of the research teams for their excellent and outstanding work in the surveys. This study was supported by National Natural Science Foundation of China (No. 30771866) and the United Nations Children's Fund (No.YH001). Conflicts of interest: none declared. This chapter is an updated version of an earlier publication in the *International Journal of Child Health and Human Development* 2019;12(2) issue with permission.

Chapter 318

MATERIALISM IN CHINESE ADOLESCENTS IN HONG KONG: PROFILES AND SOCIO-DEMOGRAPHIC CORRELATES

***Daniel T. L. Shek^{1,*}, PhD, FHKPS, BBS, SBS, JP,

ABSTRACT

Although youth development models suggest that materialistic beliefs have a negative impact on adolescent development, empirical studies in this area are scarce. Based on a sample of 2,474 high school students in Hong Kong, this study examined the profiles of materialism and socio-demographic correlates of adolescent materialism. Results showed that more than a quarter of the respondents agreed that earning money is more important than other things. Significant proportions of the respondents also agreed that adolescents in Hong Kong were materialistic. However, the respondents perceived themselves to be less materialistic as compared to adolescents in Hong Kong. Regarding socio-demographic correlates of materialism in adolescents, correlation and regression analyses showed that age, gender, parental education, and family intactness were associated with adolescent materialism. Multiple regression analyses further showed that age, gender, and family intactness were significant predictors of adolescent materialism.

INTRODUCTION

The quest for material possession is a feature of the contemporary world with several contributing factors. First, under Capitalism, there is a basic emphasis on material possession. Without material possession, the economy will shrink. In order to push up the GDP, people are persuaded and encouraged to buy commodities which essentially leads to the development of the “consumption” culture. Second, with technological advances, there are many new products such as smartphones, personal computers, and fancy electronic devices. Through aggressive marketing strategies, group pressure, and actual needs, possession of such devices is regarded as trendy and a symbol of identity. Hence, many people, particularly young people “chase” after such new products. Third, with the global issue of poverty (i.e., lack of material possession), people tend to develop the mentality that it is better to have more material possession which can give them a sense of security.

How might materialistic mentality influence adolescent development? In different cultures, over-emphasis on materialism has been regarded as problematic for human development. For example, in the Christian and Catholic traditions, spiritual values are upheld while material values are downplayed. With specific reference to the Chinese culture, materialism is also deemphasized in different social philosophies. In Confucianism, focus is placed on non-material virtues than material possession. In Buddhism, material possession is regarded as illusory and the focus is on transcendence of sensory and material urges. In Taoism, the focus is on harmony and non-material experience such as meditation and harmony with nature.

In different youth developmental models [1], there is also an emphasis on the importance of spiritual values. In the model proposed by the Search Institute, there is an emphasis on positive values which are not materialistic in nature. In particular, the value of “restraint” is the contrary of sensory pleasure and material consumption. In the 5C and 6C models [2, 3], character, compassion, and care are developmental ideals which are non-materialistic in nature. In the positive youth development constructs proposed by Catalano et al. [4], spirituality is a PYD construct which can promote the positive development of young people. This construct is in line with the existential approach which focuses on the importance of life meaning and transcendental development in human development. In the “being” approach, spirituality and character are closely related to the process of thriving which represents the healthy and holistic development of adolescents [5, 6].

According to Huta and Ryan [7], there are two motives underlying human happiness. On the one hand, happiness is determined by hedonic motives where a person seeks instant pleasure and comfort through different means, such as physical activities (e.g., shopping and drinking). On the other hand, happiness can be brought forth by eudaimonic motives where happiness is determined by one’s intention to achieve development, excellence, authenticity, and meaning [8, 9, 10, 11]. Based on this framework, materialism can be regarded as hedonic motive which leads to short term happiness only. Similarly, Peterson and colleagues [12] also differentiated hedonic orientation (i.e., life pleasure) from eudaimonic orientation which includes life of engagement and life of meaning. Again, hedonic motives basically underlie materialistic values and behavior.

Materialism is a hallmark of Capitalism. With particular reference to Hong Kong, it is a melting pot of Western influences and traditional Chinese values. Historically, Hong Kong

has also served as an international financial center focusing on business, finance, and trade. Under the Basic Law, the Capitalistic system would continue for 50 years since the handover in 1997. With this backdrop, Shek and Siu [13] argued that materialism is a risk factor for adolescent development in Hong Kong. Developmentally, over-emphasis on materialism would lead to non-holistic development and selective focus on instrumental or utilitarian values.

Although adolescent materialism is an important developmental issue, there are relatively few studies in this area, particularly in the Chinese context [14]. One notable exception is the work by Shek, Ma, and Lin [15] who developed the 21-item Chinese Adolescent Materialism Scale based on the data collected from 1,658 Chinese high school students. Confirmatory factor analyses finally suggest a three-factor model with 19 items (e.g., “unless I can make a lot of money, I won’t respect myself”; “the most important objective in a woman’s life is to marry a rich man”; “possession of money can make people happy”; “no money, no dignity”) underlying three dimensions (including “acquisition centrality,” “materialistic possessions,” and “hedonistic pursuit”). Using five items derived from the Chinese Adolescent Materialism Scale, Shek and Lin [16] examined adolescent development in different domains, including materialism, egocentrism, character strengths, and moral development. The present paper is based on the data collected by this scale.

To understand character and moral development in Chinese high school students in Hong Kong, a series of studies have been conducted by a team of researchers at The Hong Kong Polytechnic University [16-20]. This paper utilized the data collected in the study of Shek and Lin [16]. There are several research objectives in this paper. First, it attempted to examine the materialistic beliefs in Chinese high school students in Hong Kong. Besides perceived materialistic beliefs in high school students, their perception of the materialistic beliefs in Hong Kong adolescents in general was also explored. Second, we compared high school students’ perceptions of their own materialistic attitudes and those of Hong Kong adolescents in general. In the social psychology literature, there are research studies showing that one tends to see oneself as more positive than other people [21]. Hence, we examined this hypothesis in the present study. Finally, as there are few studies examining psychosocial correlates of materialism, we examined how materialistic beliefs in adolescents are related to age, gender, family intactness, and economic disadvantage in Chinese high school students in Hong Kong.

OUR STUDY

The data for the present study were derived from a large-scale study examining their character traits, psychosocial competencies, social behavior, family life, and school life of Chinese high school students in Hong Kong [16]. A total of 20 local secondary schools participated in the study, with seven schools admitting students with high academic performance (i.e., Band 1 schools), nine schools admitting students with average academic performance (i.e., Band 2 schools) and six schools admitting students with low academic performance (i.e., Band 3 schools). According to the school size, three to five classes of students were randomly selected to join the study. We recruited 2,474 students (Mean age = 14.76, SD = 1.82; 1,271 females and 1,123 males) in this study, with 1,336 junior high school

students and 906 senior high school students. Regarding the economic background of the participants, 239 students were on welfare, who could be regarded as experiencing economic disadvantage.

We obtained consent from the school, parents, and students before collecting the data. During data collection, students were requested to complete a questionnaire containing measures of character attributes, psychosocial competencies, social behavior, family life, and school life. Adequate time was provided to the students. A trained research assistant was present throughout the questionnaire administration process.

Instruments

The abridged version of the Chinese Adolescent Materialism Scale [15] was employed in this study to assess the materialistic beliefs of the respondents. Based on theories and research studies on materialism, 21 items assessing adolescent materialism were designed which showed adequate reliability and validity. In this study, five items from the different dimensions of the scale were employed to assess materialistic beliefs in the respondents. These items included: a) “making money is more important than any other things”; b) “I believe that money is everything”; c) “the rich can get respect from others”; d) “I would abandon some principles for the sake of money”; and e) “the amount of money one makes is a fundamental indicator of one’s success”. A 5-point Likert scale was used, with the response options of “strongly disagree = 1”, “disagree = 2”, “neither agree nor disagree = 3,” “agree = 4,” and “strongly agree = 5.”

To assess the respondents’ perceptions of materialism in adolescents in Hong Kong, these five items were used to capture the related views. The items included: a) “Hong Kong adolescents think that making money is more important than any other things”; b) “Hong Kong adolescents believe that money is everything”; c) “Hong Kong adolescents think that the rich can get respect from others”; d) “Hong Kong adolescents would abandon some principles for the sake of money”; and e) “Hong Kong adolescents believe that the amount of money one makes is a fundamental indicator of one’s success”. Five response options were used, including “strongly disagree = 1,” “disagree = 2,” “neither agree nor disagree = 3,” “agree = 4,” and “strongly agree = 5.”

Data Analyses

We used Statistical Package for Social Sciences Version 25 (IBM Corp., Somers, NY, USA) to carry out to answer the questions of the study. First, descriptive statistical analyses based on percentages were performed to understand the responses of the participants to the abridged version of the Chinese Adolescent Materialism Scale. Besides, perceptions of the respondents regarding materialistic beliefs amongst adolescents in Hong Kong in general were examined. Second, respondents’ views of their own materialistic attitudes and perceptions of the materialistic attitudes of Hong Kong adolescents in general would be compared using matched-sample ANOVAs. For the socio-demographic correlates, Pearson correlation analysis, linear regression, and multiple regression analyses were performed.

FINDINGS

For the first research objective, we conducted descriptive statistical analyses to understand the profiles of materialistic beliefs amongst the respondents via percentage responses. In Table 1 to Table 3, the responses of the students to the items in the 5-item abridged scale in the total, junior form, and senior form samples are presented. There are two observations. First, roughly one-third of the respondents believed that earning money is more important than other things. Second, compared to junior high school students, senior high school students held higher levels of materialistic beliefs than did junior high school students. In Table 4 to Table 6, the respondents' perceptions of the materialistic beliefs in general Hong Kong youth population are outlined. Two observations can be highlighted from the findings. First, high proportions of high school students perceived that adolescents in Hong Kong were materialistic. Second, more senior high school students perceived that young people in Hong Kong were materialistic.

To understand whether there were differences between respondents' perception of their materialistic beliefs and those of general adolescents in Hong Kong, several ANOVAs were carried out (Table 7). Results showed that there were statistically significant differences between perceived materialism in the respondents and perceived materialism in Hong Kong adolescents on materialism, $F(5,4887) = 362.900$, $p < .001$, partial eta squared = 0.27. For univariate effects (ANOVA), results similarly showed statistically significant differences between the two perceptions in the scores of each item ($p < 0.001$) and of the composite score ($p < 0.001$). In short, the respondents saw themselves as less materialistic than did Hong Kong adolescents in general.

Table 8 shows the correlations among different variables. While materialistic beliefs in the students were positively correlated with age and family intactness, the related scores were negatively correlated with gender, father education and mother education. However, there was no correlation between student materialism and economic disadvantage. Linear regression analyses were conducted for each predictor separately. As shown in Table 9, except for economic disadvantage, all other variables (age, gender, father education, mother education, and family intactness) significantly predicted student materialism. In short, male students showed higher scores than did female students. Both higher paternal education and higher maternal education predicted lower materialism scores of students. Students from non-intact families (i.e., non-first marriage families) were more materialistic than students from intact families (i.e., first marriage families).

To understand the relative contribution of different predictors to materialistic belief scores, multiple regression analysis was further conducted to predict student materialism from student age, gender, father education, mother education, family intactness, and economic disadvantage (Table 10). Results showed that after controlling other variables, student materialism was positively predicted by age and family intactness and negatively predicted by gender. In other words, older students tended to have higher materialism than did younger students. Male students had higher materialism than did female students. Students from non-intact family had higher materialism than did students from intact family. There was no predicting effect of father and mother education and economic disadvantage on student materialism, when controlling other variables.

Table 1. Perception of materialistic beliefs in the respondents (total sample)

Items	1	2	1+2	3	4	5	4+5	Mean	n

DISCUSSION

Despite the importance of the topic of materialism in adolescent development, research studies in this area are surprisingly little. As such, the current study was conducted to understand materialistic beliefs in Chinese high school students in Hong Kong. In particular, we assessed students' perceptions of materialistic beliefs in themselves as compared to adolescents in general. Besides, we also explored the socio-demographic correlates of materialistic beliefs in Chinese high school students in Hong Kong. The current study is pioneering in the field of adolescent materialism as no similar studies have been conducted before.

Based on the responses of the participants to the abridged version of the Chinese Adolescent Materialism Scale, we examined the profiles of materialistic beliefs in high school students in Hong Kong. Several observations can be highlighted from the findings. First, amongst junior secondary school students, roughly one-quarter of them (27.4%) agreed that earning money is more important than other things. The related proportion was higher in senior high school students (33.8%). Besides, roughly one-quarter of the senior high school students agreed that owning money can earn the respect of other people. These observations are disturbing because many students employed money or material possession to be a yardstick to define success and personal achievement. In future, studies should be conducted to examine how materialistic beliefs might contribute to the developmental outcomes in adolescents.

Interestingly, when the participants were asked about materialistic attitudes amongst Hong Kong adolescents in general, the participants saw that quite a high proportion of Hong Kong adolescents showed materialistic attitudes: 40% and 49% of junior and senior high school students agreed that Hong Kong adolescents defined success in terms of richness, respectively; 42.1% and 50.2% of junior and senior high school students agreed that Hong Kong adolescents equated money with respect from others, respectively. ANOVAs results also revealed that the participants saw themselves to be less materialistic than adolescents in Hong Kong in general. In other words, students generally perceived that they were less materialistic as compared to adolescents in general. This observation is generally in line with

the social psychology literature that people tend to see themselves as better than others (i.e., social desirability effect).

Regarding sociodemographic correlates of materialistic beliefs in Chinese adolescents, several observations can be highlighted. First, older adolescents showed higher materialism; senior high school students showed stronger endorsement of materialistic beliefs than did junior high school students. There are several factors contributing to this observation. First, when adolescents grow older, their understanding of the importance of money would increase. Second, students in senior forms may actually spend more, hence underscoring the importance of money in the lives of adolescents. Third, older adolescents may be more susceptible to peer influence in material possession which may be used to define their identities.

Regarding gender difference in materialistic beliefs, findings showed that being male was associated with a higher level of materialistic beliefs. There are several possible explanations for this. First, as males are the breadwinners of the family, they would attach higher importance to money and material possession. Second, as males are more instrumental and pragmatic, they would see monetary and material possession to be more important. In future study, we should further examine how such gender differences would be translated into gender differences in other areas, such as psychological well-being and interpersonal relationships.

The present findings also showed that both paternal and maternal education were related to adolescent materialistic beliefs. There are two possible explanations of the findings. First, higher parental education implies higher income for the family, which would reduce the importance of material possession. Second, parents with higher education might nurture their children to develop in a more holistic manner, particularly to look at the world from different angles. Further research is needed to understand how parents would socialize the children, particularly in terms of development of happiness from a hedonic or eudemonic motive.

Finally, materialistic beliefs were higher in high school students in non-intact families than intact families. There are studies showing that parenting and family functioning are less favorable in non-intact families than in intact families. The present study shows that development of materialistic beliefs is adversely affected in non-intact families which is not systematically examined in previous studies. Furthermore, non-intact families might suffer from economic problem which may underscore the importance of material possession. However, as the present findings do not show any relationship between economic disadvantage and materialistic beliefs in adolescents, more research in this area is needed.

Although the present study is a pioneering study in the field, there are several limitations. First, although the sample was large, the students were not randomly selected. Hence, generalizability of the findings should be carefully examined. It is suggested that random samples should be used in future studies. Second, as only five items were used to assess materialistic beliefs, it would be helpful to use more items in future study. Of course, in a survey assessing many constructs, the issue of overloading the respondents should be carefully considered. Finally, regarding the socio-demographics of adolescent materialism, as the effect sizes were not large, there is a need to replicate the findings.

ACKNOWLEDGMENTS

The series of studies on character and moral development in high school students in Hong Kong are financially supported by Wofoo Foundation. ABSTRACT

While there are studies on materialism and egocentrism based on self-reports of adolescents, there are very few studies focusing on teachers' perceptions of materialism and egocentrism in their students and adolescents in general. In this study, teachers' perceptions (N = 568) of materialism and egocentrism in Chinese adolescents were examined. Findings showed that many teachers perceived that their students and adolescents in Hong Kong showed materialistic beliefs. A significant proportion of teachers also perceived that their students and adolescents in Hong Kong generally showed worrying signs of egocentrism. While background demographic factors (age, gender, religious orientation and teaching grades) were not related to adolescent materialism, teachers' perceptions of their students' egocentrism were related to teaching grades and teachers' perceptions of egocentrism in adolescents in general were related to age, gender, and teaching grades.

INTRODUCTION

Adolescence is an important stage where young people develop beliefs and values about themselves and the world. With cognitive maturation and enlargement of the social circle, adolescents form views about themselves, including their own characteristics and unique features. Besides, adolescents also form views about the world, such as ideological beliefs and philosophies. Amongst the beliefs and values formed by adolescents, there are two important areas to be considered. The first belief is on how adolescents view material possession and money (i.e., materialistic beliefs). With more contact with the world (e.g., buying lunch at school and using money at their own discretion) and peer influence (e.g., it is trendy to possess a pair of limited edition of sports shoes), adolescents begin to form beliefs about material possession and money. Obviously, the development of healthy attitude to material possession is important for adolescent thriving behavior. If adolescents hold unhealthy values, they may engage in delinquency behavior such as theft, shoplifting, and compensated dating to earn quick money in order to get material possession.

Shek, Ma and Lin [1] showed that a high level of materialism was related to a higher level of egocentrism but lower levels of morality, spirituality, and empathy. In different youth development models, particularly in the field of positive youth development [2], it is commonly emphasized that “being” (i.e., non-material values) such as character strengths are important to adolescent development. For example, in the developmental assets proposed by the Search Institute, the developmental assets focus on values and virtues which are non-materialistic in nature [3]. In the 5C/6C models on youth development [4, 5], competence, confidence, character, compassion, connection, and contribution are non-materialistic nature. In the existential literature, the theory proposed by Victor Frankl [6] does not focus on “will to sex and aggression” and “will to power”; rather, it focuses on “will to life meaning” which is non-materialistic in nature. In fact, materialism is a by-product of Capitalism which focuses on the importance of material possession and consumption [7].

Another adolescent belief is adolescents’ thoughts and experiences when comparing to others. If one always over-estimates one’s ability and devaluates others’ views, one would develop a “superiority complex”. On the other hand, if one always under-estimates one’s belief and over-emphasizes others’ views, one would develop “inferiority complex”. Furthermore, if one looks at things only from his or her own perspective without considering others’ views, it is a self-centered orientation. On the other hand, if one looks at things from others’ perspectives, it is other-centered orientation. Cognitively speaking, children tend to look at things from one’s perspective without making reference to others’ perspectives. According to Piaget [8], children’s thinking style in late childhood is egocentric. However, with cognitive maturation, adolescents gradually know how to look at the world from one’s perceptive as well as others’ perspectives, although they initially hold distorted views about oneself and others, such as viewing one’s thoughts are superior than others [9-11]. According to Shek, Yu and Siu [12], there are two dimensions of egocentrism, including belief that one’s thought is better than others (i.e., self-conceit) and not considering the views and experiences of other people (i.e., disregard of others). Developmentally speaking, egocentrism is a normal stage in adolescent development; however, if adolescents cannot grow out of it, it would then be developmental problems to the adolescents.

With widening of the social networks during adolescents, self-centered orientation would impair interpersonal relationships. Besides, adolescent egocentrism would lead to engagement in risky behavior because adolescents believe they are exceptional. Shek, Yu, and Siu [12] showed that adolescent egocentrism was negatively related to spirituality and empathy. Conceptually, with reference to different youth development models, it is commonly asserted that taking others' perspective and sensitive to others' feelings are important for adolescent healthy development. Positive values and social competences are emphasized in Benson's developmental assets model [3]. In the 5C/6C model, it is argued that caring and compassion (i.e., consideration of others) are important. In the social-emotional perspective (e.g., CASEL's model), understanding of others' views is an important competence to be acquired by adolescents. In the character strengths perspective [13-15], social intelligence and modesty are emphasized. In the positive youth development models [16], the importance of considering others' views and experiences is highlighted.

The major drawback of the existing studies on adolescent materialism and egocentrism is that the existing studies are primarily based on self-reports of adolescents. There are several limitations of reliance on the self-report data collected from adolescents. First, it can be argued that adolescents may not have an accurate understanding of themselves because of their emerging cognitive maturity. Second, adolescents may have biases in viewing oneself, particularly because of social desirability effects such as "beauty of beholder side". Third, as self-evaluation of one's weaknesses is painful, self-report of adolescents may not be accurate. Hence, it is methodologically desirable to include the perspectives of other stakeholders (i.e., teachers) to look at the related issues. The engagement of teachers is helpful for several reasons. First, as teachers spend much time with students, they have a better understanding of their students and young people in Hong Kong. Second, through intensive interaction with students, teachers would have a good understanding of the students. Third, with professional teacher training, teachers would have a more informed judgment about the situation of their students and adolescents. With reference to Hong Kong, studies on adolescent materialism are few [7, 17, 18]. In the study conducted by Shek and colleagues [7], the finding showed that high school students perceived that adolescents showed worrying signs in materialism and egocentrism. Obviously, it would be illuminating if the views of teachers could be collected.

As there are few studies on the moral character, materialism, egocentrism, and psychosocial development in high school students in Hong Kong, colleagues at The Hong Kong Polytechnic University conducted several studies based on perspectives of adolescents, teachers, and parents [18-22]. In this paper, we used the data collected based on teachers' perceptions of materialism and egocentrism of Chinese adolescents [19] with several objectives. First, we examined the perceptions of teachers on materialism and egocentrism of high school students and adolescents in Hong Kong. Second, we examined whether materialism and egocentrism in high school students and adolescents in general are different based on the perspective of teachers. Based on the social psychology literature, it was hypothesized that teachers would see their students to be less materialistic and egocentric as compared to adolescents in the general adolescent population. Third, as there are not many studies on the psychosocial correlates of teachers' perceptions of materialism and egocentrism in their students and adolescents in Hong Kong, we tested several tentative hypotheses: a) as older people tend to be more conservative, older teachers would see their students or adolescents in general to be more materialistic or egocentric; b) as females focus more on affective relationships and they are more empathetic (i.e., less egocentric), female

teachers would see their students or adolescents to be more materialistic or egocentric as compared to male teachers; c) compared with those without religion, teachers with religious beliefs would see their students and Hong Kong adolescents to be more materialistic or egocentric; and d) as those who teach both junior and senior high school students would have better understanding of high school students, they would see their students to be more egocentric.

OUR STUDY

To understand the views of teachers on adolescent materialism and egocentrism, teachers from 11 secondary schools in Hong Kong were recruited to participate in this study ($N = 568$), with 345 female teachers (60.7%) and 216 male teachers (38%). The sample could be categorized into five age groups: 25 years or below ($n = 36$, 6.3%), 26-35 years ($n = 162$, 28.5%), 36-45 years ($n = 153$, 26.9%), 46-55 years ($n = 160$, 28.2%), and 56 years or above ($n = 49$, 8.2%). A total of 464 teachers were with teaching experiences of more than six years. Consent from the teachers was obtained before data collection.

Prior to data collection, this study was reviewed and approved by the University Institutional Review Board at a public university in Hong Kong. After getting approval from the school principals, data were collected from the teachers. In each school, we distributed the questionnaires to the school coordinator who helped to collect the completed questionnaires in sealed envelopes without revealing the identity of the respondents.

INSTRUMENTS

Teachers' perception of adolescent materialism: To assess teachers' perceptions of adolescent materialism, we modified the abridged 5-item Chinese Adolescent Materialism Scale [1] which was originally developed to assess materialistic beliefs in Chinese adolescents. These items included: a) "My students believe that making money is more important than any other things"; b) "My students believe that money is everything"; c) "My students believe that the rich can get respect from others"; d) "My students would abandon some principles for the sake of money"; and e) "My students believe that the amount of money one makes is a fundamental indicator of one's success". A five-point Likert scale was used, including "strongly disagree", "somewhat disagree", "neither agree nor disagree", "somewhat agree", and "strongly agree", with higher scores indicating higher levels of materialism.

To understand teachers' perceptions of materialism in Hong Kong adolescents in general, the same five items were used with changing perspectives. The items included: a) "Hong Kong adolescents think that making money is more important than any other things"; b) "Hong Kong adolescents believe that money is everything"; c) "Hong Kong adolescents think that the rich can get respect from others"; d) "Hong Kong adolescents would abandon some principles for the sake of money"; and e) "Hong Kong adolescents believe that the amount of money one makes is a fundamental indicator of one's success". We used a five-point Likert scale in which higher egocentrism was reflected by higher scores.

Teachers' perception of adolescent egocentrism: To assess teachers' perceptions of egocentrism in their students, we modified the abridged 5-item Chinese Adolescent Egocentrism Scale [19] which was originally developed to assess egocentrism in Chinese adolescents based on the perspective of adolescents [12]. These items included: a) "My students regard their experiences are more important than those of others"; b) "My students think that their interests are more important than those of others"; c) "My students always find justifications for their behavior"; d) "most of the time, my students think that other people's criticisms about them do not make sense"; e) "even if they make other people unhappy, my students are true to their experience". For each item, there are five response options, including "strongly disagree", "somewhat disagree", "neither agree nor disagree", "somewhat agree", and "strongly agree", with higher scores showing higher levels of egocentrism.

For teachers' perceptions of adolescent egocentrism, we modified the abridged 5-item Chinese Adolescent Egocentrism Scale [19] which was originally developed to assess egocentrism in Chinese adolescents [12]. These items included: a) "Hong Kong adolescents regard their experiences are more important than those of others"; b) "Hong Kong adolescents think that their interests are more important than those of others"; c) "Hong Kong adolescents always find justifications for their behavior"; d) "most of the time, Hong Kong adolescents think that other people's criticisms about them do not make sense"; e) "even if they make other people unhappy, Hong Kong adolescents are true to their experience". For each item, there are five response options. A higher total score means a higher level of perceived egocentrism in Hong Kong adolescents in general.

Data Analyses

The Statistical Package for Social Sciences Version 25 (IBM Corp., Somers, NY, USA) was used to perform the related analyses. First, we examined percentage findings to look at the profiles of responses of teachers to the modified version of the Chinese Adolescent Materialism Scale as well as the modified Chinese Adolescent Egocentrism Scale.

Table 1. Teacher perception of materialistic beliefs in their own students

Items	1 n (%)	2 n (%)	1+2 n (%)	3 n (%)	4 n (%)	5 n (%)	4+5 n (%)	Mean	n
My students believe making money is more important than any other things.	14 (2.5%)	140 (24.7%)	154 (27.2%)	123 (21.7%)	254 (44.8%)	36 (6.3%)	290 (51.1%)	3.28	567
My students believe "Money is everything".	45 (7.9%)	173 (30.5%)	218 (38.4%)	163 (28.7%)	164 (28.9%)	22 (3.9%)	186 (32.8%)	2.90	567
My students believe that the rich can get respect from others .	15 (2.7%)	144 (25.4%)	159 (28.1%)	153 (27.0%)	221 (39.0%)	33 (5.8%)	254 (44.8%)	3.20	566
My students believe they would abandon some principles for the sake of money.	52 (9.2%)	179 (31.8%)	231 (41.0%)	192 (34.1%)	134 (23.8%)	6 (1.1%)	140 (24.9%)	2.76	563
My students believe "The amount of money one makes is a fundamental indicator of one's success".	17 (3.0%)	128 (22.6%)	145 (25.6%)	169 (29.8%)	222 (39.2%)	31 (5.5%)	253 (44.7%)	3.22	567

Besides, teachers' perceptions of materialistic beliefs and egocentric beliefs amongst the general adolescent population in Hong Kong were examined. Second, teachers' views of the materialistic and egocentric beliefs of their students were compared with their perceptions of the materialistic and egocentric beliefs of Hong Kong adolescents in general, respectively. For the socio-demographic correlates, Pearson correlation analysis and regression analyses were performed.

Table 2. Teacher perception of materialistic beliefs in HK adolescents

Items	1 n (%)	2 n (%)	1+2 n (%)	3 n (%)	4 n (%)	5 n (%)	4+5 n (%)	Mean	n
Adolescents in HK believe making money is more important than any other things.	4 (0.7%)	58 (10.2%)	62 (10.9%)	109 (19.2%)	336 (59.3%)	60 (10.6%)	396 (69.9%)	3.69	567
Adolescents in HK believe "Money is everything".	13 (2.3%)	74 (13.1%)	87 (15.4%)	160 (28.2%)	272 (48.0%)	48 (8.5%)	320 (56.5%)	3.47	567
Adolescents in HK believe that the rich can get respect from others".	4 (0.7%)	60 (10.6%)	64 (11.3%)	107 (18.9%)	331 (58.4%)	65 (11.5%)	396 (69.9%)	3.69	567
Adolescents in HK believe they would abandon some principles for the sake of money.	10 (1.8%)	82 (14.5%)	92 (16.3%)	165 (29.1%)	276 (48.7%)	34 (6.0%)	310 (54.7%)	3.43	567
Adolescents in HK believe "The amount of money one makes is a fundamental indicator of one's success".	4 (0.7%)	47 (8.3%)	51 (9.0%)	119 (21.0%)	321 (56.6%)	76 (13.4%)	397 (70.0%)	3.74	567

Table 3. Teacher perception of egocentrism in their own students

Items	1 n (%)	2 n (%)	1+2 n (%)	3 n (%)	4 n (%)	5 n (%)	4+5 n (%)	Mean	n
My students believe their feelings are more important than the feelings of other people.	1 (0.2%)	20 (3.5%)	21 (3.7%)	71 (12.5%)	298 (52.6%)	177 (31.2%)	475 (83.8%)	4.11	567
My students believe their own benefits are more important than the benefits of other people.	4 (0.7%)	19 (3.4%)	23 (4.1%)	107 (18.9%)	335 (59.2%)	101 (17.8%)	436 (77.0%)	3.90	566
My students believe that no matter what happens, they can always justify their behaviors.	3 (0.5%)	19 (3.4%)	22 (3.9%)	83 (14.6%)	291 (51.3%)	171 (30.2%)	462 (81.5%)	4.07	567
My students believe the criticisms on them are usually groundless.	6 (1.1%)	108 (19.1%)	114 (20.2%)	188 (33.2%)	231 (40.8%)	33 (5.8%)	264 (46.6%)	3.31	566
My students are true to their own feelings even if this may upset other people.	1 (0.2%)	52 (9.2%)	53 (9.4%)	178 (31.4%)	270 (47.6%)	66 (11.6%)	336 (59.2%)	3.61	567

FINDINGS

The descriptive profiles based on percentage findings on teachers' perceptions of materialism in students, materialism in Hong Kong adolescents, egocentrism in students, and egocentrism in Hong Kong adolescents are presented in Table 1 to Table 4. First, significant proportions of teachers perceived their students and Hong Kong adolescents showed signs of materialism. For example, 51.1% and 69.9% of the teachers regarded their students and Hong Kong adolescents believed that "making money is more important than any other things", respectively. Second, more than half of the teachers perceived their students and Hong Kong adolescents in general showed signs of egocentrism. For example, the teachers believe that "their feelings are more important than the feelings of other people" (83.8% and 89.9%, respectively). Third, teachers generally perceived that materialism in their own students was lower than that in Hong Kong adolescents. Fourth, teacher perceived egocentrism in their own students to be lower than that in Hong Kong adolescents.

MANOVAs and ANOVAs were further performed to look at the third and fourth observations. Results of the one-way MANOVA analyses showed that there were statistically significant differences in materialistic beliefs between students and Hong Kong adolescents perceived by teachers, $F(5, 1123) = 33.450$, $p < 0.001$, partial eta squared = 0.130. For univariate effects, there were significant differences between teacher perceptions of students and teacher perceptions of Hong Kong adolescents at the item score ($p < 0.001$ in all items) and composite score ($p < 0.001$) levels (see Table 5). Similarly, one-way MANOVA analyses showed that teachers perceived significant difference between egocentrism in their students and Hong Kong adolescents, $F(5, 1124) = 21.379$, $p < 0.001$, partial eta squared = 0.087. For univariate effects, teacher perceptions of students and Hong Kong adolescents were statistically significantly different over Items 2, 4, and 5 ($p < 0.001$) and the composite score ($p < 0.001$) (see Table 6).

Table 4. Teacher perception of egocentrism in HK adolescents

Items	1 n (%)	2 n (%)	1+2 n (%)	3 n (%)	4 n (%)	5 n (%)	4+5 n (%)	Mean	n
Adolescents in HK believe their feelings are more important than the feelings of other people.	2 (0.4%)	10 (1.8%)	12 (2.2%)	45 (8.0%)	351 (62.0%)	158 (27.9%)	509 (89.9%)	4.15	566
Adolescents in HK believe their own benefits are more important than the benefits of other people.	4 (0.7%)	11 (1.9%)	15 (2.6%)	56 (9.9%)	364 (64.3%)	131 (23.1%)	495 (87.4%)	4.07	566
Adolescents in HK believe that no matter what happens, they can always justify their behaviors.	2 (0.4%)	8 (1.4%)	10 (1.8%)	63 (11.2%)	337 (59.6%)	155 (27.4%)	492 (87.0%)	4.12	565
Adolescents in HK believe the criticisms on them are usually groundless.	4 (0.7%)	37 (6.5%)	41 (7.2%)	145 (25.6%)	318 (56.2%)	62 (11.0%)	380 (67.2%)	3.70	566
Adolescents in HK are true to their own feelings even if this may upset other people.	2 (0.4%)	16 (2.8%)	18 (3.2%)	92 (16.3%)	348 (61.5%)	108 (19.1%)	456 (80.6%)	3.96	566

Note. ****p* <.001; ^Adjusted Bonferroni value = .008.

Pearson correlation analyses showed that teachers' perceptions of materialism in students and materialism in Hong Kong adolescents were not correlated with age, gender, religion, and teaching grade of teachers. In contrast, teachers' perception of egocentrism in their students was related to teaching grade whereas perceived egocentrism in Hong Kong adolescents was correlated with age, gender, and teaching grade (see Table 7).

Note. **p* <.05, ***p* <.01, ****p* <.001.

^aAged 25 or below = 1, Aged 26-35 = 2, Aged 36-45 = 3, Aged 46-55 = 4; Aged 56 or above = 5.

^bMale = 1, Female = 2; ^cHaving religion = 1, Having no religion = 2.

^dTeaching junior forms (S1-S3) = 1, Teaching senior forms (S4-S6) = 2, Teaching both junior and senior forms (S1-S6) = 3.

Regression analyses were conducted for each predictor separately. Results showed that there were no prediction effects of age, gender, religion, and teaching grade on materialism in students and materialism in Hong Kong adolescents perceived by teachers (Tables 8 and 9). Teachers' perceived egocentrism in students was only predicted by teaching grade ($F(1, 545) = 4.527, p < 0.05$) but not by other predictors (Table 10). Teachers' perceived egocentrism in

Hong Kong adolescents was predicted by age ($F(1, 558) = 7.039, p < 0.01$), gender ($F(1, 559) = 4.482, p < 0.05$) and teaching grade ($F(1, 545) = 12.344, p < 0.001$) but not religion (Table 11).

DISCUSSION

Although adolescent materialism and egocentrism are important aspects of adolescent development, few Chinese studies have been conducted. In particular, no study has been conducted to look at the related issues from the perspective of significant-others of adolescents, particularly teachers. Against this background, we conducted this study to examine teachers' perceptions of materialism as well as egocentrism in their students and adolescents in Hong Kong. We also compared the perceived differences between students taught by the respondents and Hong Kong adolescents in general on materialism and egocentrism. Furthermore, as there are very few studies on the socio-demographic correlates of perceptions of materialistic and egocentric beliefs in Hong Kong high school students and adolescents in general, we explored several tentative hypotheses in this study. Because there are very few related studies in the field, this is a pioneer attempt in studying adolescent materialism and egocentrism.

Based on the teachers' responses to the modified version of the Chinese Adolescent Materialism Scale, we observed several phenomena. First, around 45% of the teachers perceived their students believe that "no money, no dignity". Similarly, around 45% of the teachers perceived their students believe that "the amount of money one makes is a fundamental indicator of one's success". Second, more than half of the teachers perceived that adolescents in Hong Kong hold materialistic beliefs: around 70% of the teachers perceived that "adolescents in HK believe making money is more important than any other things"; around 70% of the teachers perceived that Hong Kong adolescents equated money with dignity and regarded money as the criteria of success. These findings are worrying because the over-emphasis on material possession would be detrimental to adolescent development. In future, we should further examine how materialistic beliefs influence adolescent development, particularly on the development of character strengths and virtues.

For adolescent egocentrism, the picture is even more worrying. More than two-third of the teachers perceived that their students are egocentric: around 84% of the teachers perceived that their students regarded their feelings to be more important than those of other people; 77% of the teachers perceived that their students regarded their own benefits are more important than the benefits of other people. Furthermore, most of the teachers perceived that adolescents in Hong Kong were egocentric: around 87% of the teachers perceived that Hong Kong adolescents regarded that their benefits are more important than those of others; around 87% of the respondents perceived that adolescents always have justifications for their behavior. These findings suggest that adolescents should be helped to balance the emphasis on superiority of one's views and feelings while respecting the views and experiences of other people.

Regarding perceptions of teachers regarding materialism and egocentrism in their students and Hong Kong adolescents, the findings showed that teachers generally had relatively positive perceptions of their students as compared to adolescents in general – students were seen as less materialistic and less egocentric as compared to adolescents in Hong Kong. This observation is interesting and it is in line with the previous findings that adolescents saw themselves as less materialistic than did adolescents in general [23].

Several observations can be highlighted from the findings on the socio-demographic correlates of teachers' perceived materialism and egocentrism beliefs in Chinese adolescents.

First, socio-demographic correlates were not related to teachers' perceived materialism and egocentrism of their students and Hong Kong adolescents in general. Second, with more teaching exposure (i.e., teaching more grades), teachers tended to perceive that their students were more egocentric. One possible explanation is that teachers might have a more in-depth understanding of their students when they teach junior and senior form students. Third, age, gender, and teaching grades were related to teachers' perceptions of egocentrism of adolescents in Hong Kong. The positive relationship between age and perceived egocentrism is consistent with the conjecture that people with older age are more conservative and they are more critical of young people. Regarding gender, as females attach more emphasis on interpersonal relationship, they would also be more critical of egocentric behavior in adolescents as compared to males. Concerning grade teaching, we can interpret that those with more teaching exposure would understand their students better, hence having a higher level of perceived egocentrism amongst Hong Kong adolescents. However, as the present hypotheses are tentative in nature, there is a need to further refine them in future studies.

Although the present study is a pioneer study in the field, there are several limitations. First, as the sample was not randomly selected, we should be cautious to examine the generalizability of the findings. Further replication of the findings based on random samples is in order. Second, as only abridged scales (i.e., five items) were employed, it would be theoretically and empirically enriching if longer scales could be used. Third, regarding the socio-demographic prediction of teachers' perceived adolescent materialism and egocentrism, the findings are tentative and inconclusive. Hence, there is a need to refine the related hypotheses and theoretical bases. Finally, the origin of materialism and egocentrism in adolescents was not covered in the present study. In the area of materialism, there are studies suggesting that socialization within the family context plays an important role in the development of different motives for happiness in adolescents [24-28]. Hence, it would be exciting to explore how family socialization contributes to the development of materialism and egocentrism in adolescents further.

ABSTRACT

In this chapter we aimed to examine the influence of family mealtime environment on children's behavior, in addition to styles of parenting and family functioning. This study adopted a two-wave longitudinal design. Data was collected over two rounds, 12 months apart, from 470 parents with children aged three to six. Parents completed measures on their parenting style, family functioning, children's behavior, family meal frequency, family feeding practice and mealtime television. Family feeding practice and parenting style were found to be associated with children's behavior. Family feeding practice mediated between parenting style and children's behavior. Family mealtime environment is important on children's behavior.

INTRODUCTION

Young children under parental care are expected to dine at home as part of the general family routine. It is argued that family mealtime behavior is likely to be consistent with other patterns of family social interaction which are associated with child outcomes [1].

There have been a number of cross-sectional studies on the association between family meal frequency and child behavior in preschool and primary school children. For example, higher family meal frequency was associated with reduced externalizing behavior problems and higher prosocial behavior in preschool/primary school children [2, 3]. Among adolescents aged 11 to 18 years, a cross-sectional study found a negative association between family meal frequency and substance abuse, after controlling for family connectedness [4]. The association between family meal frequency and adolescent problem behavior has also been reported in some longitudinal studies. For example, family meal frequency at baseline was found to be negatively associated with substance use among female adolescents in a 5-year longitudinal study and the mean age of participants was 17.2 at follow-up [5]. More recently, a 3-year longitudinal study found that family meal frequency was negatively associated with substance-use, drinking, physical violence and running away among adolescents [6]. However, there were few longitudinal studies on the association between family meal frequency and child behavior outcomes among preschool/primary school children.

Many scholars theorized about the association between family meal frequency and child psychosocial outcomes. Family mealtimes offer natural “face-to-face sit-together” chances for parent-child communication, parent monitoring of child activities, and sharing of feelings [1]. Parents can be role models for table manners, respect and sharing [5]. Family meals within the context of family routine can provide stability, a developmental protective factor [7].

There are some limitations with previous studies. First, most findings on preschool/primary children were based on cross-sectional studies, and it was not possible to establish causal relationship between family meal frequency and behavior outcomes. Second, many studies failed to consider the roles of family functioning or parenting variables. Family functioning involves cohesion (emotional closeness amongst family members) and communication (sharing of ideas and affect among family members) in the family [8]. Parenting style can be conceived along two dimensions: demandingness (parent acting as socializing agent) and responsiveness (parent recognition of child individuality) [9]. Authoritative parenting is high in demandingness and responsiveness and associated with positive child outcomes. Authoritarian parenting is high in demandingness but low in responsiveness, while permissive parenting is just the opposite [10]. Authoritarian parenting and permissive parenting were associated with poorer child outcomes [11]. Family meal frequency might be confounded with variables like family functioning or parenting style [12]. Third, more frequent family meals might arise from closeness among family members. Family meal frequency might mediate between family relationship and child behavior outcomes, and such role should be examined [12]. Fourth, most studies measured family meal frequency as a composite score for all family members. The contribution of individual family members (e.g., father, mother) should be examined.

Other contextual family mealtime environment variables, including mealtime television viewing and family feeding practice, warrant attention in understanding the association between family meal frequency and child outcomes. Sustained television viewing was found

to be positively associated with child behavior problems in preschool children [13] though mealtime television viewing was not examined specifically in this study. Mealtime routines were related to children's behavior outcomes. For example, parental rigid demands for the child to finish all food served might lead to child behavior problem and conflict with parents. Disorderly mealtime routine was related to neglect and disregard [1]. The impact of these mealtime environment variables on child outcomes should be investigated.

This study addressed the limitations of previous studies. First, it adopted a longitudinal design to provide evidence on causal relationships. Second, it collected data on parenting style and family functioning. The relationship between family mealtime environment variables and family functioning/parenting variables could be investigated. Third, family mealtime environment variables including mealtime television viewing and family feeding practice (type of food served, mealtime behavior management) were investigated. Fourth, to examine the unique contribution of family members, the presence of family members was individually recorded. Finally, to test the cross-cultural applicability of previous findings, the present study targeted Chinese families with preschool children. The results would enable comparison of findings across cultures to map out universal and culture-specific factors.

This study collected two rounds of data from Chinese families with preschool children to examine the influence of family mealtime environment variables (family meal frequency, mealtime television viewing, family feeding practice), parenting style and family functioning on child behavior. Literature review guided this study to examine (i) the direct effect of family mealtime environment variables on child outcomes, in addition to parenting style and family functioning variables; and (ii) family mealtime environment variables as mediators between family functioning/parenting style and child outcomes. The hypotheses were:

- 1) Family mealtime environment, family functioning and parenting style would be associated with child behavior problems.
- 2) Family mealtime environment would mediate between family functioning/parenting style and child behavior problems.

OUR STUDY

This was a longitudinal survey. The two rounds of data collection were 12 months apart. The study only included (i) parents who were Cantonese-speaking (Cantonese being the usual language/dialect used at home for 89.5% of the Hong Kong population) [14]; and (ii) parents whose children were attending preschools at the time of the study. Parents with children with global developmental delay, physical, severe hearing or visual impairment or Autism Spectrum Disorder were excluded. Since there were two rounds of data collection, parents with children in the final year of their preschools were excluded as their children would have left preschools by the second round of data collection.

Two strategies were used to recruit the participants coming from 24 preschools from 15 of the 18 districts in Hong Kong. First, the investigators used their personal network and contacted organizations providing preschool education. Five organizations nominated preschools within their organizations to participate, and 18 preschools participated. Second, a research assistant made phone calls to invite preschools throughout Hong Kong. Six out of

400 participated. In each participating preschool, the number of participating parents ranged from nine to 141.

The ethics committee of The Hong Kong Polytechnic University approved the study. After getting consent from the preschools and parents, the parent questionnaires were distributed through the preschools. At both rounds of data collection, parents completed the questionnaires at a time and place of their own convenience, and returned the completed questionnaires to the preschools in sealed envelopes.

Measures

Parenting Style and Dimension Questionnaire – Short Form (PSDQ-SF) [15] – Parents completed this 32-item 5-point Likert scale with a validated Chinese version for Hong Kong parents [16] measuring authoritative, authoritarian and permissive parenting styles (e.g., emphasizing the reasons for rules, exploding in anger towards child, spoiling child). A total score was calculated for each style. Higher scores indicated more frequent adoption of that particular parenting style.

Chinese Family Assessment Instrument (C-FAI) [17] – This 33-item measure assessed family functioning (e.g., mutual consideration, harmonious family relationship). It yielded five sub-scales, namely, communication, mutuality, conflict and harmony, parental concern and parental control. The parent version was adapted from the original version for completion by adolescents. Parents rated each statement along a 5-point scale (1: *completely agree*; 5: *completely disagree*). The negatively worded-items were reverse scored. Lower scores represented more harmonious family functioning in all sub-scales.

Hong Kong Parent Feeding Questionnaire (HKPFQ) – This 35-item questionnaire assessed parent knowledge, attitude, cooking and feeding practices with regard to their children (e.g., mealtime regularities, diet profile). Parents rated each item on a 3-point scale. A higher score suggested healthier feeding practices. This scale has been used with Hong Kong parents of preschool children in a recent infant and young child feeding survey [18].

Family meal frequency – Parents had to report the frequency of family members present at family dinner over a week. The number of days within a week that mother ate with the target child was summed up to generate a new variable. A similar variable was created for fathers. Another variable on frequency of grandparents eating with the target child was created by summing up all the meals that grandparents (paternal and maternal) ate with the target child.

Frequency of mealtime television viewing – Parents were requested to report the frequency of dinner time television viewing over a week. The total number of nights the television was on was summed up to form a new variable.

Eyberg Child Behavior Inventory (ECBI) [19] – This was a 36-item measure of parental perception of disruptive behavior (e.g., temper tantrums) in children aged two to 16 years. It included two scales, Intensity scale and Problem scale. ECBI-Intensity measured the frequency of problem behavior on a 7-point rating scale. ECBI-Problem measured the extent to which the parents were concerned about the behavior (1: *yes*; 0: *no*). A validated Chinese version was available [20].

Family background - Parents were asked to supply information on their age, family type, education level, employment, family income and social welfare status. Family income was recoded into a dichotomous variable (at/above versus below median household income).

Data Analysis

In this study, the Round 1 and Round 2 variables were measured at the individual level. Owing to the cluster (preschools) nature of the data set, multilevel mediation modelling [21] was used to appropriately model the error structure, treating “preschool” as the random factor. This method allows the testing of mediation effects in clustered datasets. We started by examining the direct effects of Round 1 variables (family mealtime environment, parenting style and family functioning) on Round 2 child behavior outcome. Then, the mediation effect of Round 1 family meal frequency, mealtime television viewing, family feeding practice between Round 1 family functioning/parenting style and Round 2 child behavior outcomes was tested. In the analyses described above, the outcome variables were Round 2 child behavior as measured by ECBI-Intensity and ECBI-Problem. As child gender and family income were found to be associated with child behavior [22, 23], they were controlled for in the analysis.

FINDINGS

The demographic characteristics of the participants and the scale descriptive statistics are shown in Table 1. Table 2 shows the bivariate correlations. As C-FAI mutuality was highly correlated with C-FAI communication ($r = .83$, $p < .001$, $R^2 = .68$) and C-FAI conflict and harmony ($r = .72$, $p < .001$, $R^2 = .52$), C-FAI mutuality was excluded in the following analyses to control for multicollinearity. The direct effects are shown in Table 3.

Table 1. Demographic characteristics of participants and mean and standard deviation scores of scales (N= 470)

	Number	Percentage	
Sex of target child - boy	232	49.40%	
Sex of target child - girl	238	50.60%	
Relationship of participant to target child - mother	372	79.15%	
Relationship of participant to target child - father	94	20.00%	
Relationship of participant to target child - grandparents	4	0.85%	
Target child living with both parents	417	88.72%	
Target child living with mother only	21	4.47%	
Target child living with father only	9	1.91%	
Target child not living with parents	22	4.68%	
Mother's education – junior secondary or below	120	25.53%	
Mother's education – senior secondary or above	347	73.83%	
Father's education – junior secondary or below	133	28.30%	
Father's education – senior secondary or above	327	69.57%	
Mother employed	244	51.91%	
Father employed	442	94.04%

C-FAI Parental control	0.30 (-0.71, 1.32), $p = .557$	0.17 (-0.12, 0.46), $p = .261$
Frequency of fathers eating with child	-0.16 (-0.98, 0.67), $p = .710$	-0.01 (-0.24, 0.23), $p = .942$
Frequency of mothers eating with child	0.43 (-0.60, 1.47), $p = .413$	0.19 (-0.10, 0.49), $p = .199$
Frequency of grandparents eating with child	0.21 (-0.19, 0.62), $p = .300$	0.10 (-0.02, 0.22), $p = .089$
Frequency of mealtime television viewing	-0.02 (-0.80, 0.77), $p = .970$	0.21 (-0.02, 0.43), $p = .076$
Family feeding practice	-0.58 (-0.92, -0.23), $p = .001$	-0.07 (-0.16, 0.03), $p = .168$

The Sample

In Round 1, among 2,492 consent forms distributed, 923 parents consented to participate. Eleven participants were either outside Hong Kong or had changed schools when data was collected. There were 663 sets of complete data out of 912 data sets collected [24]. In Round 2, there were 676 parents with complete data. There were 470 parents with complete data in both waves, which provided the basis for the reported analysis.

Participants with complete and incomplete data in both rounds differed. Participants with complete data in both rounds attained lower scores on Round 1 C-FAI conflict and harmony, $t(859) = 2.67$, $p = .008$, and Round 1 authoritarian parenting, $t(847) = 2.07$, $p = .043$. Among those with complete data in both rounds, there was a higher proportion of families with monthly income above HK\$20,000, $\chi^2(1) = 8.05$, $p = .005$.

Frequency of Child Behavior Problems (ECBI-Intensity)

Round 2 ECBI-Intensity scores were associated positively with Round 1 authoritarian and permissive parenting and negatively with Round 1 family feeding practice and child gender (Table 3). As Round 1 permissive parenting was negatively associated with Round 1 family feeding practice ($b = -0.78$, $z = -7.01$, $p < .001$), the mediating effect of Round 1 family feeding practice as a mediator between Round 1 permissive parenting and Round 2 ECBI-Intensity scores was tested. The positive indirect ($z = 3.00$, $p = .045$) and total ($z = 5.12$, $p < .001$) effect of Round 1 permissive parenting on Round 2 ECBI-Intensity scores were significant. Round 1 authoritarian parenting was negatively associated with Round 1 family feeding practice ($b = -0.17$, $z = -2.66$, $p = .008$). The mediating effect of Round 1 family feeding practice as a mediator between Round 1 authoritarian parenting and Round 2 ECBI-Intensity scores was tested. The positive indirect ($z = 2.09$, $p = .037$) and total ($z = 3.95$, $p < .001$) effect of Round 1 authoritarian parenting on Round 2 ECBI-Intensity scores were significant.

.001) effect of Round 1 authoritarian parenting on Round 2 ECBI-Intensity scores were significant. In short, higher frequency of child behavior problems was associated with more authoritarian and permissive parenting, less healthy feeding practice, and the child being male. Family feeding practice was a mediator between permissive/authoritarian parenting and frequency of child behavior problems.

Parent Concern over Child Behavior Problems (ECBI-Problem)

Round 2 ECBI-Problem scores were negatively associated with child gender and positively associated with Round 1 permissive parenting (Table 3). More parent concern over child behavior problems was associated with the child being male and more permissive parenting.

DISCUSSION

In terms of Hypothesis 1, the results indicated that family mealtime environment variables had direct contributions to child behavior, after controlling for family functioning, parenting style, and family income. Specifically, healthier feeding practices were associated with lower frequency of child behavior problems. The longitudinal design of the present study provided further support for the causal relationship between family feeding practices and child behavior outcomes. The emphasis on healthy food (rather than the often more appealing unhealthy food) and regular meal routines implies a sense of self-regulation which is conducive to positive behavior outcomes. The results confirmed that mealtime routines were related to children's mental health [1]. The results also concurred with literature and provided support for the negative effect of authoritarian and permissive parenting on child behavior [11].

With regard to Hypothesis 2, the results provided evidence of family mealtime environment variables as mediators of parenting style on child behavior outcomes. Permissive parenting styles negatively influenced child behavior outcomes through family feeding practices. Parents with permissive styles were more likely to allow unhealthy feeding practices (e.g., unhealthy food, lax meal routines), which then predicted more child behavior problems. Authoritarian parenting rigidly demanding the child to finish all food served might lead to parent-child conflict and child problem behavior [1].

The present study illuminated on parenting practices for Hong Kong Chinese families with preschool children. The findings generally concurred with the international literature on the impact of parenting style and family mealtime environment on children's outcomes. Family mealtime environment variables reflected actual parenting practices such as type of food eaten, arrangement of meal routines, and management of mealtime behavior. The results indicated that actual parenting practices and parenting styles were both influential on child developmental outcomes.

Limitations

First, the family and parenting measures were only based on parent reports. Second, the reporting parents were mostly mothers, while views from both parents should be useful to identify possible couple differences in parenting styles or practices, as well as their impact on child and family outcomes. Third, the sample did not include preschools in all administrative districts of Hong Kong, and is not adequately representative of the Hong Kong population. Fourth, participants with incomplete data were more disadvantaged and less positive in parenting practices than those with complete data. These should be fully considered in the interpretation of the data.

CONCLUSION

This study underscores the importance of considering family mealtime environment in understanding family influence on child development. Family mealtime environment variables and parenting style variables contributed directly to child behavior. Family feeding practice was associated with parenting style, and family feeding practice mediated the effect of parenting style on child outcome. This study reinforces the efforts to conduct longitudinal studies in families. Such attempts in this study successfully generated meaningful causative information that can directly enrich health education and the practice of professionals working with young children. The findings allow for evidence-based assertions that parenting styles are associated with child outcomes. It will be helpful for parents to learn to be responsive to their children, harbor realistic expectations on their children and be reasonably demanding on their age-appropriate performance. Parents should try to create more opportunities to cultivate healthy and pleasant family atmosphere. Parents should set limits and rules for appropriate mealtime behavior, provide a variety of food, and let the child decide how much to eat and what to eat [18].

ABSTRACT

Utilizing the life course perspective, historical time and events that have influenced family development, delay of social timing of family development, linked lives that supported families and emergence of different modes of the families in Hong Kong were examined. The analyses showed several changes in the structures and functions of families in Hong Kong during the past few decades, which include: 1) reduced birth rate due to the success of the "birth control" campaign, the change of the conception of childbearing and the rising burden associated with child rearing; 2) delay of social timing of marriage and parenthood as more females participated in the labor force; 3) increased

* Corresponding Author's Email: janet.leung@polyu.edu.hk.

involvement of grandparents and foreign domestic helpers in taking care of children; 4) parents are heavily affected by the educational opportunities and achievement of their children, resulting in the mushrooming of “monster parents” (helicopter parents) who “hover” over their children’s lives; 5) emergence of “DINK” (Double Income, No Kids) families; 6) an increase in cross-border marriages; 7) an increasing trend of marital disruption in families; and 8) a growing demand for the recognition of non-traditional forms of families. The implications of these family developments to family research and practice were discussed.

INTRODUCTION

Family is regarded as the “vital component of the society” [1]. It is the basic unit of production, reproduction and perpetuation, protection of members from external forces, socialization, nurturing for the next generations, mutual support and emotional security [2, 3]. However, the socio-economic and cultural transformations in Hong Kong in the past few decades have brought about dramatic changes to families. The reduction of family size, an increasing number of mothers entering into the labour force, the rise of divorce rate, an emergence of “DINK” (double income with no kids) families, the blossoming of “monster parents” (helicopter parents) who “hover” over their children’s lives [4] are examples illustrating the inevitable structural and functional changes that have happened in the families in Hong Kong. While some changes are the result of global transformation of families, some changes are unique to the social, political and economic conditions in Hong Kong. Against such macro social changes, several questions should be asked - What have happened to the cohorts who are now the main actors of the families? What were the historical, social and cultural transformations that have influenced the family structures and functions? What were the changes of the families during this transition?

The generation theorists have offered special labels to different cohorts born after the World War II, namely the “Baby Boomers” (1943-1960), “Generation X” (1961-1981), and “Generation Y” or “The Millennial” (1982-2000) [5, 6]. According to such views, each cohort showed very special characteristics due to the social changes that happened during those eras. The cohort studies provided an insightful lens for scholars and policy makers to understand how social changes affected these generations, and how one generation affected the other generations. However, they did not specifically employ the family as the basic unit of study, and they paid inadequate attention to the changes of the family structures and functions. Moreover, the studies took US as the backstage and the observations might not be applicable to non-American cultures, as culture is an important determinant of the development of families [7]. To understand the changes of families during the transition in Hong Kong, the life course perspective [8, 9] provides an useful angle to examine the historical and social transformations that have influenced Hong Kong family development in the past few decades.

THE LIFE COURSE PERSPECTIVE

As suggested by Bengtson and Allen [10], the life course perspective is a “contextual, processual, and dynamic approach to the study of change in the lives of individual family

members over time, and of families as social units as they change over historical periods” [10]. Elder [8] concretely gave a definition to the life course as “age-graded life patterns embedded in social structures and cultures that are subject to historical change” [8]. Three basic components are intrinsic to this definition: age-graded life patterns, social structure and culture, and historical change. Regarding the age-graded life patterns, they are formulated by the ontogenetic development of individuals as well as the stages of family life cycle. Life span theories, such as Erikson’s [11] psychosocial stages of development, give an account of the ontogenetic development of individuals. A family life cycle portrays the stages of family development by examining different family developmental tasks in response to the development of its members [12]. Concerning the social structure and culture, there are four dimensions: social structural context, social construction of meaning, cultural context and the interplay of macro-micro levels of analysis [10]. Finally, historical time is the “events, periods, or eras dominated by watershed geopolitical or economic events” [10]. In summary, the life course perspective emphasizes the interplay of life span development, historical time and events, as well as the social context. White and Klein [13] regarded the life course perspective to focus on the “sociological meaning of development” [13]. Hence, the evolvement of the life course perspective put the two lines of inquiries, including life span development (i.e., the intra-individual changes) and social development (i.e., the extra-individual changes), together.

PARADIGMATIC THEMES OF THE LIFE COURSE PERSPECTIVE

Elder and his colleagues [8, 9, 14] suggested four paradigmatic themes that are central to the life course perspective, including a) human lives in historical time and place, b) the timing of lives, c) linked or interdependent lives, and d) human agency in the choice making and social constraints. These themes do not only constitute the essential elements of the life course perspective; they also identify important mechanisms through which the history and social contexts influence human development.

Human lives are influenced by the historical events and social contexts. In the life course, people of different ages are exposed to different historical worlds and may have different impacts in their lives. Thus, history brings the “cohort effect” to a particular birth cohort when there are social changes that affect and differentiate their life patterns from other cohorts [8].

The timing of lives emphasizes the concept of “social timing” that defines the start and the termination of social roles, their duration and sequence in respect to the relevant age expectations and beliefs [8]. The social timing of lives is essential as it gives the structure to the life course where age norms, sequences, durations of life events and trajectories are embodied.

Linked or interdependent lives are the social relationships with kin, friends and the significant others across the life span [8]. It is expected that one’s life course would knit with those of the others sharing the significant relationships [9]. Finally, as differentiated from social determinism that human agency is determined by the social environment, the life course theory respects the choices of individuals in determining their live course. However, there are social constraints and age-graded norms that may create restrictions. Individuals

may need to make their own choices with the interpretations of the opportunities and constraints [8].

HONG KONG FAMILIES IN TRANSITION

Hong Kong has undergone rapid demographic and social changes that have strong impacts on the family development during the past few decades. Furthermore, the Government policies also provided structural opportunities and constraints to individuals that may affect their marital and parental trajectories [15]. Thus, identifying the historical development as well as the policies implemented during the past decades would be important for understanding the families in transition.

The Birth Control Campaign in the 1970s: “Two is Enough”

The baby boom in the post-war period as well as the influx of immigrants from mainland China resulted in a rapid increase of the population from 1950s to 1970s in the last century in Hong Kong. There was a need for the Government to control the population growth. Against this background, the Family Planning Association of Hong Kong launched the “Two is enough” campaign to arouse public concern on birth control in 1975. The Association used a series of propaganda and educational means to encourage families to have two children at most, accompanied with other birth control services such as the use of contraceptives, sterilization and pregnancy termination operation. The campaign not only resulted in a sharp decrease in the fertility rate (from 3,459 children per 1,000 women in 1971 to 2,047 in 1980) in Hong Kong; it also altered the Chinese beliefs of “child-bearing” in the Hong Kong society. In the traditional Chinese culture, childbearing was considered as a natural biological imperative in the Chinese families. The Chinese cultural focus of “*chuan zong jie dai*” (continuation of posterity) and “*ji hou xiang deng*” (to have descendants for lighting the joss stick and lantern) was considered as the primary function of the family. Thus, contraception and termination of pregnancy were considered as anti-natural, immoral and anti-familial concepts that were not generally embraced by the Chinese values. The consequences of “*sha sheng*” (killing lives) and “*jue hou*” (prohibiting posterity) were social taboos in the traditional Chinese culture.

However, the “Two is enough” campaign constructed a new conception of childbearing that birth could be “controlled”. Birth control was no longer considered as an anti-natural and anti-familial concept that resulted in “*sha sheng*” or “*jue hou*”, but a new connotation of “family planning”. With the advancement and popularity of contraceptive methods, people are more acceptable to use these methods to “control birth”. The frequent use of contraceptive practice (almost every time of sexual intercourse) was 86%, 79.5% and 74.8% in 2002, 2007 and 2012 respectively. The rate of induced abortion was 26.3%, 20.6% and 14.1% in 2002, 2007 and 2012 respectively [16]. Though there were decreasing trends of frequent use of contraceptive practice and induced abortion during the past decade (probably due to the use of other means of contraception), the figures were still striking. The campaign not only helped to legitimize the use of contraception and termination of pregnancy, but also altered the

Chinese cultural value of “continuation of posterity”. In a survey on understanding the change of family values, it was found that the young generation showed less agreement on “having descendants to carry on the family name is very important” than did their parents [17].

The attitudinal changes on childbearing as well as common practice of contraceptive methods have facilitated the couples to have fewer kids, or even have no kids. From the statistics of the Census and Statistics Department [18, 19], it was found that the average domestic household size has gradually decreased from 4.3 in 1981 to 2.9 in 2014. The total fertility rates also dropped rapidly over the past three decades. There were only 927 children per 1,000 women in 2001, which were far below the replacement level of 2,100 children per 1,000 women [20]. “The small family culture” [21] characterized by very few kids and child-centered family practice was evolving.

Compulsory and Free Education

In 1971, the Government launched the policy of “six-year compulsory and free education” in Hong Kong. The policy was expanded to nine years in 1978 and free education was further expanded to twelve years in 2008. The policies provided dramatic changes on the educational attainment of citizens in Hong Kong. Before that, it was not easy for children to receive education to the secondary level, especially for females. With the traditional cultural discourse of “man is superior to woman” (*nan zun nu bei*) in the Chinese society, the chance for females to receive education was less. However, the implementation of “compulsory and free education” policy became a turning point for educational attainment of women, where women were treated the same as men in receiving free and compulsory education. The policy has three important impacts: higher educational attainment of women, increased women’s participation in the labor force, and rising aspirations for career prospect for women. It was found that female students studying in the programs funded by the University Grants Committee (sub-degrees, undergraduates, postgraduates) had been increased from 15,609 (32.9%) in 1986/1987 to 52,598 (53.9%) in 2014/2015 [22]. The related percentages of females had surpassed the percentages of males from 1996/1997 onwards [19]. In particular, the percentage share of female students enrolled in postgraduate and undergraduate programs were 60.6% and 54.7% respectively, which further exceeded the percentages of males enrolled in these programs [19]. When considering women’s participation into the labor force, there was a steady increase of females entering into the labor force. In the past three decades, the female to male ratio in labor force has increased from 0.58 in 1986 to 0.95 in 2014 [19]. The gap between the labor force participation between males and females was narrowing. Furthermore, there were increasing numbers of women occupying higher positions in the labor market. The numbers of females occupying the posts of managers/administrators and professionals have increased from 403,000 and 377,000 respectively in 1993 to 1,065,000 and 861,000 respectively in 2010 [19]. Women in Hong Kong have been gaining better career prospects.

Open-Door Economic Policy of Mainland China since 1978

The open-door economic policy of mainland China is an important milestone of the changes of the economic structure in Hong Kong. Before that, Hong Kong was dominated by the manufacturing industries which required unskilled or semi-skilled labor. Women were commonly engaged in low-wage factory work which required a low educational standard and skills. With the open-door economic policy of mainland China since 1978, there was a great expansion of tertiary industries such as banking, finance, legal advice and consultation, information technology, etc. A high level of knowledge and professional skills were required. Managerial and professional positions increased and required employees with higher educational attainment and career commitment. As mentioned, this attracted more females to fill the managerial and professional positions [19].

The open-door economic policy of mainland China has also facilitated the emergence of cross-border marriages, extra-marital affairs across the border, and educational problems of children across the border [23].

Engagement of Foreign Domestic Helpers

In the face of the labor policy of the Philippines to encourage and promote export of labor in the form of overseas Filipino workers, the Hong Kong Government has opened up the legal immigration channels for the families to hire foreign domestic helpers (FDH) since 1974. The employer families need to sign up a two-year standard employment contract with the foreign domestic helpers and apply for a visa from the Immigration Department.

Figure 1. The occurrence of historical events during 1961-1980 in Hong Kong that influenced family development.

With the economic prosperity of Hong Kong in the 1980s and 1990s, the employment of foreign domestic helpers was becoming very popular in Hong Kong. The number of foreign domestic helpers increased from 172,119 in 1998 to 330,650 in 2014. Among them,

Philippino and Indonesian maids accounted for 52.3% and 45.3% of the number of foreign domestic helpers, respectively [19].

In summary, Figure 1 illustrates the occurrence of the historical events during 1961-1980 in Hong Kong that influenced family development.

The Delay of Timing in Different Stages of Family Development

The popularity of education resulted in the delay of school completion age of adults. A crucial effect is that there was a time delay for a person to enter the work force. The labor force participation rate of males and females aged 15-24 dropped significantly from 65.5% and 61.7% respectively in 1986 to 8.0% and 8.6% respectively in 2014 [19]. Obviously, the delay of timing of school completion implies prolonged dependency of adult children to their families.

Besides, women nowadays have a higher chance to hold jobs with better career prospect. To sustain the requirement of their jobs, they need to invest longer working hours, more work commitment, educational advancement and on-job training. According to the human capital theory [24], increased economic opportunities may influence the marriage pattern and decision of women. The career commitment and human capital investment happened early in the life course of adulthood may delay the decision of women to engage in marriage. Wong [25] provided support for this view which showed the relationship between the rising educational attainment and employment opportunities of women and the postponement of timing of marriage in Hong Kong.

During the past three decades, it was found that the median ages of first marriage of males and females have risen from 27.0 and 23.9 respectively in 1981 to 31.2 and 29.1 respectively in 2014 [22]. With the normative sequence that marriage precedes parenthood, the delay of timing of marriage definitely delays the timing of parenthood.

To understand the timing of parenthood, it is important to differentiate the concepts of the biological timing from the social timing. Biological timing of parenthood refers to biological capability of individuals to remain reproductive. Biological capability sets a non-negotiable deadline to parenthood, with the loss of fecundity of women [15]. Normally, the childbearing ages of women are between 15 and 49 years of age [22]. Social timing of parenthood takes into account of the readiness of an individual to enter into the parental role. Marital status, life transition, social expectations and constraints would propose a relative “social timing” [15]. In the past three decades, there was a disparity between biological timing and social timing in marriage and parenthood in Hong Kong. The couples were biologically “fit” to enter marriage and parenthood, but the social timing to enter into the social roles of being married and as parents lagged behind. There are three consequences of the delay of timing of parenthood. First, women gave birth to a child at an older age. The median age of women at the first birth rose from 25.1 in 1981 to 31.3 in 2014 [19]. Second, the couple did not have many children. The changes of cultural beliefs on “child-bearing” resulted from the “birth control” campaign also fascinated the delay of timing of child-bearing. Third, some parents might consider having no children due to the high risk of dystocia and anxiety for bearing an abnormal child in late pregnancy, as well as the anticipated difficulties in finance and effort to rear a child.

Interestingly, there has been a social discourse generated by the mass media that rearing a child lifelong requires HK\$4,000,000 (roughly US\$500,000).

“Linked Lives” --- The Support but Indulgent Care of Grandparents and Foreign Domestic Helpers

In the life course perspective, linked lives are essential for a family to establish significant relationships with others across the life span [9]. Among all, two significant relationships are critical for the Hong Kong families: the family of origin as well as foreign domestic helpers.

The families of origin are important supportive systems of the nuclear families. Grandparents played an important role of taking care of their grandchildren and were often regarded as “substitute parents” [21]. Although grandparents might not live together with their adult children due to the limited space in Hong Kong, the non-cohabitation did not restrict the genuine needs of the adult children as well as the grandparents’ enthusiasm to take care of their grandchildren. In a household survey commissioned by the Family Council in 2013, it was found that 58.3% of the respondents agreed on the high values of roles played by grandparents in family life, and 65.3% agreed that grandparent’s involvement was appreciated by the adult parents [26].

The opening-up of legal immigration channels for foreign domestic helpers from the Asian countries by the Hong Kong Government has facilitated more women to enter into the labor force, while foreign domestic helpers manage the family housework as well as take care of the elderly and the children at home. Though employing foreign domestic helpers in childcare was regarded as the reluctant choice of the working parents, it became an actual reality of many families in Hong Kong [27].

As there was an increasing trend of mothers participating in the labor force, grandparents were more involved in taking care of their grandchildren. However, the parenting style of grandparents might be different from that of the parents [28] and this might result in intergenerational conflicts and disputes [29]. Moreover, the involvement of grandparents might intrude into the family life of the adult child’s family and create power dynamics between the grandparents and adult parents. Intergenerational discrepancies in parenting styles might generate opportunities for the children to manipulate the family members in order to get the most benefits [28].

As a consequence, there was a creation of “4-2-1 indulgence” culture (i.e., four grandparents and two parents spoiling one child) [30]. In addition to the popularity of employing foreign domestic helpers to do housework and take care of the children, there were totally seven adults serving one child. The child becomes the “little emperor” of whom the family adults give superior attention, human and material resources [31]. The adolescents today are labeled as the “spoilt generation” who show signs of narcissist traits [32]. They are also regarded as “Hong Kong Kids” who are “unable to look after themselves, have low emotional quotient and even lower adversity quotient.” [33]. This would make them grow up in a “greenhouse” and become more egocentric [34].

Due to the very few children in the family as well as the “*wang zi cheng long*” (expecting the son to become a dragon) beliefs embedded in the Chinese culture, the parents have high

expectation about their children's future [3]. They were heavily affected by the educational opportunities and achievement of their children, hoping that their children could be competitive in their future. The parents paid great effort and plenty of resources to nurture their children, with the expectation that they could win "at the starting line". As a consequence, they were highly involved and intervened frequently in their children's lives. Different terminologies of "helicopter parenting" [35], "monster parenting", "lawnmower parenting" [36] have been used to describe the over-parenting or over-nurturing phenomenon. The parents have faced much stress in nurturing their children and may further affect the parent-child relationship. In a household survey commissioned by the Family Council in 2013, it was found that 72.0% of the parents felt more tired than before, 63.2% expressed that their large part of life was controlled by the child's needs, and 60.4% suffered from the severe lack of personal time [26].

Choices of the Couples – Emergence of Different Forms of Families

Though there were historical events and social constraints shaping the life course trajectories of the families, the couples could still make their own choice in constructing their families. There were three types of families that are prevalent in Hong Kong: the "DINK" families, cross-border marriages and the divorced families.

"DINK" means "Double income with no kids". "DINK" families are childless or childfree families with the couples participating in the labor force. In the past, the phenomenon was considered as "deviant" and "abnormal", especially in the Chinese culture that continuation of posterity is emphasized. Childlessness was considered as "*jue hou*" (prohibiting posterity) in the traditional Chinese culture which was regarded as a taboo. It was up to 1970s and 1980s that "child-free" was considered as an "alternative lifestyle" that families could have outside the traditional norms of a nuclear family [37]. According to the Family Planning Knowledge, Attitude and Practice in Hong Kong Survey in 2012, it was found that there were 23.4% of the respondent families reported childless (excluding those families with involuntary infertility or sub-fecundity). There were also 7.1% of females and 5.3% of males who preferred to be "child-free" [16].

Besides personal choices, there are social constraints that might affect the couples to choose childlessness. Work is one of the barriers for married couples to have children. Career advancement, employment opportunities, long-hour work culture are considerations of the married couples to remain "childless" [38]. Age is another important factor that the couple would prefer childfree, especially those entering middle adulthood. Rowland [39] highlighted two components for the age-related fertility decline: a reducing probability of conceiving and an increasing risk of spontaneous abortion. Furthermore, the high risk of dystocia as well as anxiety for bearing an abnormal child in late pregnancy would forbid the couples to consider childbearing. In addition, rearing a child requires huge responsibilities and financial costs that have become a social constraint of childbearing. Jones [40] suggested the ideology of having "quality" child and financial costs of childbearing were factors that lower the desire of childbearing among the married couples in Pacific Asia. Among the respondent couples who did not want to have children in the Family Planning Knowledge, Attitude and Practice in

Hong Kong Survey in 2012, 43.3% of females and 42.0% of males suggested that the financial constraint was the main reason for childlessness.

The open-door economic policy of mainland China has facilitated the emergence of the cross-border marriages in Hong Kong. In 2014, there were 26,330 cases of cross-border marriages in Hong Kong, of which 20,698 marriages registered in Hong Kong, occupying 36.7% of the total marriages registered that year [19]. There were some unique features arising from the cross-border marriages, which include the marriages between a young wife and an old husband, split families and pseudo single parent (either children live with father in Hong Kong while mother stays in China, or the children stay with mother in China while father resides in Hong Kong), and cross-border education of children [41, 42]. Though the cross-border marriage has been a common form of marriage in recent years, concerns and problems such as adjustment difficulties of migrant mothers and children, increased risk for marital stability and harmony, accommodation problems in Hong Kong with limited living space, parenting difficulties, problems in children's education, poorer care, nurture and modeling of the children, social isolation and higher risk of spousal violence [23, 42, 43] are emerging.

When looking at the divorce rate figures, the crude divorce rate has been increasing steadily from 0.76 in 1984 to 3.1 in 2013, with the first time of decrease to 2.8 in 2014 [19, 44, 45]. It is worth noting that divorce as a percentage of marriage remained high (33% to 35%) during the past five years. One reason accounting for the change was the direct influence of the Western romantic conception of marriage that has eroded the Chinese cultural values of familism [46]. The conception of marriage in Hong Kong has been moving away from a traditional and patriarchal mode to a modern and egalitarian one [47]. Instead of preserving a long-lasting conjugal relationship based on the Confucian virtues of familism, the couples would consider divorce when they experienced marital dissatisfaction. The temptation of extramarital affairs also constituted the increase of divorce rate [46, 48]. Moreover, the general acceptance of divorce by the public makes divorce become a "means" to solve marital dissatisfaction. In a household survey commissioned by the Family Council, 63.2% of the respondents agreed that if a married couple did not have children, divorce was the best solution for them when they could not live harmoniously. Even if the couple has children, 32.3% still agreed that divorce was the best choice if they could not live together agreeably [26].

Apart from the increase of DINK families, popularity of cross-border marriages and high divorce rate, there is a growing demand for the recognition of non-traditional forms of families. Similar to the Western world, the voice of LGBT (lesbian, gay, bisexual and transgender) communities to recognize their rights for marriage, adoption of children and formation of family was blooming. In 2013, the court ruling on transgender marriage has raised the hopes for sexual minorities to pursue their rights in marriage and family formation [49]. At the same time, it has brought great challenges to the traditional values of marriage and family. As mentioned by the dissenting judge of the court case, to consider a transsexual's marriage a right implies "a radical change to the traditional concept of marriage" [50]. The traditional forms of marriages are confronted with strong pressure, which may bring revolutionary changes to the family forms, values and systems. Table 1 summarizes the family changes in the transition under the paradigmatic themes of the life course perspective.

Table 1. Summary of family changes in Hong Kong under the paradigmatic themes of the life course perspective

Paradigmatic themes	Family changes
Humans live in historical time and place	- The birth control campaign in 1975: “Two is Enough” - Compulsory and free education - Open door economic policy in mainland China - Legal immigration channels for foreign domestic helpers - Reduced birth rate - Change of the conception of childbearing and less emphasis on the Chinese value of “continuation of posterity” - Delay of social timing of marriage and parenthood - More mothers participated in the labor force - The employment of foreign domestic helpers for childcare and family housework
The timing of lives	- Delay of social timing of marriage and parenthood - Reduced birth rate - Emergence of “DINK” (Double Income, No Kids) families
Linked or interdependent lives	- Increased involvement of grandparents and foreign domestic helpers in taking care of the child - Indulgence parenting with seven adults (four grandparents, two parents and one foreign domestic helper) in nurturing one child in a family - Parental stress due to high expectation on education and achievement of their children - The mushrooming of “monster parents” (helicopter parents) who “hover” over their children’s lives
Human agency in choice making and social constraints	- Emergence of “DINK” (Double Income, No Kids) families - Increase in cross-border marriages involving young wives and old husbands - Increasing trend of marital disruption in families - A growing demand for the recognition of non-traditional forms of families

IMPLICATIONS TO FAMILY RESEARCH AND PRACTICE

With reference to the analyses based on the life course perspective, the families in Hong Kong are exhibiting several changes. These included: 1) reduced birth rate due to the success of the “birth control” campaign, the change of the conception of childbearing and the rising burden associated with child rearing; 2) delay of social timing of marriage and parenthood as more females participated in the labor force; 3) increased involvement of grandparents and foreign domestic helpers in taking care of the children; 4) parents are intensely affected by the educational opportunities and achievement of their children, resulting in the mushrooming of “monster parents” (helicopter parents) who “hover” over their children’s lives; 5) emergence of “DINK” (Double Income, No Kids) families; 6) an increase in cross-border marriages involving young wives and old husbands; 7) an increasing trend of marital disruption in families; and 8) a growing demand for the recognition of non-traditional forms of families. The changing family trends draw attention of social scientists, researchers and clinical practitioners on family research and practice.

The life course perspective provides thoughtful ideas in understanding how the historical and social contexts influence the development of family life patterns. This is especially meaningful in the Chinese families, as familism is central in the Chinese culture [51, 52]. It is insightful and important if longitudinal panel studies across cohorts were conducted to

examine how different historical and social contexts influence family beliefs and life patterns in the life course trajectories.

As suggested by Elder and Shanahan [9], the temporal location of reproductive cycle greatly influenced the family life cycle. Early childbearing would hasten the cycle and shorten the distance between generations. In contrast, late childbearing may decelerate the cycle and reduce the age similarities across generations. In Hong Kong, the delay of social timing of marriage and parenthood is salient and affects the family life patterns across adjacent generations. Thus, it is important to examine the influence of temporal location and timing of family life cycle on human development and life patterns.

The life course perspective not only sketches the temporal changes in the patterns of family life cycle, it also portrays the changes of roles within the family. The social contexts have influenced greatly on the roles and division of labor in the family. With more mothers participating in the labor force and grandparents and foreign domestic helpers offer support in childcare and housework, their roles within the family are changing. It is interesting and important to examine the changes in roles and functions of different members in families, as well as the family dynamics such as family boundary, rules, power and interactions, etc. The importance of linked lives across the life span and generations should catch more research attention. Furthermore, timing also matters to the role and identity change of the family members. The implications of marriage and parenthood may vary in accordance with the social timetable, age norms and age-graded sanctions [9]. Ebaugh [53] used the term “role exit” to describe an identity change in response to the transformation of roles in the life span. Indeed, temporality of family roles may be an emerging area that needs to be explored.

The prevalence of divorce and child-free couples has strong impact on the family life development across generations. However, it is criticized that the life cycle which only focuses on reproduction and parenting has “limited value as a way of viewing the lives and developmental trajectories of children and adults because it does not apply to never married, non-parent, or divorced persons, all of whom have become increasingly common” [9]. In fact, divorce may imply multiple families in a person’s life which may lead to interwoven roles and complex kin relationship. Regarding the child-free families, there is a concern about the changes of the family life patterns as well as the developmental life tasks of the couples. “Parenthood” has been expected as an important developmental task in one’s life span, which may result in generativity in the middle age [54]. Thus, the absence of parenthood in the family life cycle may have great impact on their members. The effects of the divorce and DINK to the family members may need to be further researched.

From a macro perspective, the changes of forms and patterns of the families may have significant impact on the social values, structure and functions. For instance, the delay of marriage and parenthood would result in a reduced birth rate of Hong Kong, which may further bring the future risk of the aging population. The cross-border marriages may bring the demographic, cultural and social concerns to the society, as the education, value systems and lifestyles in China may be different from those in Hong Kong. Social scientists need to be sensitive to the changes and explore the impact on the society as a whole. In fact, family research in Hong Kong with respect to these areas is grossly inadequate [55].

Regarding family practice, the “small family culture” characterized by very few kids and child-centered family practice is evolving in Hong Kong. The “seven adults serving one kid” phenomenon (four grandparents, two parents and one foreign domestic helper) has happened in the Hong Kong families, with more resources being allocated for the child development,

but at the same time the children are over-parented and over-protected. Further research to examine the impact of over-parenting on child development in Hong Kong is urged. Besides, it is important for family practitioners to understand the new forms of parenting in the Chinese families and to provide parenting education to the family members. In particular, grand-parenting is becoming more and more popular in Hong Kong when both parents enter the labor force in the recent decades. However, grandparent education programs are not well developed in Hong Kong. Thus, it is important to develop effective training strategies on grandparent education.

Furthermore, the life course perspective suggests that historical events, age-graded experiences and role identity may influence individual's life span and family life development across generations. In the swiftly changing world, grandparents, parents and children may share different cultures and experiences. These may influence the family values, dynamics and interaction among the family members. The discrepancies of perceived roles and expectation among the family members, as well as the differences in parenting styles and practices between the two generations may result in family conflicts [28]. Thus, family practitioners should be sensitive to the intergenerational conflicts that may generate between the grandparents and adult parents, and resolve the conflicts when these arise. It is necessary to explore the collaborative roles between grandparents and adult children of which complementary parenting as well as respectful participation could be nurtured [56].

In view of the prevalence of the cross-border marriages in Hong Kong, there are concerns to the adjustment of the families, educational needs of the children as well as the high risks of family instability. Supportive and counseling services are definitely essential. However, the differences in social welfare policies across the border make the service difficult to be delivered to the cross-border families. Negotiation with the Chinese Government is necessary so that more resources and services can be provided to help the cross-border families. Again, we need more research in this area to illuminate the issues involved.

The rising trend of divorce has set an alarm to the family development in Hong Kong. Family breakdown and dysfunctions has detrimental effects to parental distress and adolescent development. Marital counseling and post-divorced parenting education programs are necessary. Besides, family mediation services are important.

Last but not least, new family forms and patterns challenge the conventional values of the Chinese culture and social expectation to the families. Family practitioners should be sensitive to the cultural changes and work against the social disharmony and stigmatization that may arise. Obviously, we need more research to understand how the public look at these "non-conventional" families and examine the needs, problems and resilience facing by such families. Besides, training family practitioners need to be sensitive to the "macro" social conditions instead of just focusing on the "micro" dyadic or family issues.

CONCLUSION

Hong Kong families have undergone dramatic changes in these few decades. The life course perspective provides a sociocultural lens for social scientists to explore the family life cycle and patterns of the Hong Kong families. The success of birth control campaign, free and compulsory education, increased work opportunities for women in the labor market have

brought forward the delay of social timing of marriage and parenthood. Linked with the support of grandparents and foreign domestic helpers in childcare and family management, the indulgence culture of rearing the children and over-parenting was created. The increase of divorced families, cross-border marriages, DINK families and emergence of non-traditional forms of families also became one of the concerns of family development in Hong Kong. The social account of family life course in Hong Kong is just the beginning of the long journey to explore the family life development in the Chinese communities. More scientific research should be conducted to explore how historical time and socio-cultural contexts influence family life course across generations. With the belief that people can “work out their life course in relation to established, institutionalized pathways and their regulatory constraints” [9, p.706], the studies of family life course in the Chinese communities may open a door for scholars and social scientists to have a better understanding of the Chinese families in the transition.

Chapter 322

**SUBJECTIVE OUTCOME EVALUATION
OF THE TIN KA PING P.A.T.H.S. PROJECT
IN CHINA: VIEW OF THE STUDENTS**

ABSTRACT

Utilizing the client satisfaction approach, the present paper reports the program participants' perceptions of a positive youth development program (Tin Ka Ping P.A.T.H.S. Project) in China. Upon the completion of the program, altogether 7,289 Secondary 1 and 2 students completed a valid and reliable questionnaire (Form A) to rate on different aspects including program content, program implementer, and program effectiveness. As anticipated, most students evaluated all the three aspects positively. Grade differences were observed, with Secondary 1 students reporting higher satisfaction on program content, program implementer, and overall satisfaction than did their Secondary 2 counterparts. Furthermore, perceived program content and implementer quality predicted perceived program effectiveness. In short, the findings underscore the effectiveness of the Tin Ka Ping P.A.T.H.S. Project launched in the academic year 2015-2016.

INTRODUCTION

Since the beginning of the “open-door policy” in the early 1980s, China has developed rapidly. China has become the world’s second largest economy and is forecasted to surpass the United States by 2030 [1]. Such an economic growth goes hand in hand with the urbanization of the contemporary Chinese youth communities. Accordingly, how such an economic transition in China has shaped the psychological development of Chinese adolescents attracts growing interest in the research community. For instance, utilizing the cross-temporal meta-analytic data from thousands of Chinese youth, Xin and associates [2, 3] revealed that urbanization level was a significant positive correlate of adolescents’ anxiety level, depressive symptoms, and mental illness across cohorts, and the mental health of young people in China had deteriorated throughout time.

In view of such a backdrop, the Ministry of Education [4] published “The Outline of Education Guide for Pupil’s Mental Health”. One key strategy entails the permission for primary and secondary schools to hire mental health teachers to implement mental health education and offer counseling service to the students. There is, nonetheless, still a lack of systematic teaching resources for these mental health teachers regarding how psychosocial competencies of the students can be strengthened. As such, there is an urgent need to develop related curriculum materials based on the positive youth development (PYD) approach. According to Damon [5], problem prevention alone is not enough to promote healthy youth development and it is important to discover and nurture adolescents’ strengths, talents, and potentials.

With reference to Hong Kong, adolescents also display problems such as substance abuse, materialism, and bullying [6]. Nonetheless, Shek and Yu [7] highlighted the paucity of robustly evaluated, multi-year PYD programs in Hong Kong. Against such a backdrop, a multi-year project entitled “Positive Adolescent Training through Holistic Social Programs” (Project P.A.T.H.S.), funded by The Hong Kong Jockey Club Charities Trust, was launched in 2005. The Project P.A.T.H.S. which comprises two tiers is a comprehensive PYD program tailored for junior secondary-schoolers in Hong Kong. While the Tier 1 Program represents a curriculum-based intervention targeting the general junior secondary-schooler population, the Tier 2 Program was catered to adolescents with greater psychosocial needs. Results from a multitude of evaluation studies [8] corroborate the effectiveness of the Project P.A.T.H.S. over the years in promoting the holistic youth development alongside eradicating risk behavior in junior secondary students in Hong Kong.

Despite the remarkable achievement of the Project P.A.T.H.S., we have to ask whether the related programs can be successfully applied in other Chinese communities [9]. Funded by the Tin Ka Ping Foundation, the first phase of the program entitled “Tin Ka Ping Positive Adolescent Training through Holistic Social Program” (Tin Ka Ping P.A.T.H.S. Project) was embarked on in four schools in East China (Shanghai, Suzhou, Changzhou, and Yangzhou) since 2011. This pioneer project in China was well-received as evidenced by findings derived from both subjective outcome evaluation [10] and objective outcome evaluation studies [11]. Accordingly, started from the academic year 2015-2016, the second phase of the Tin Ka Ping P.A.T.H.S. Project targeting both junior and senior secondary schoolers was launched in 30 secondary schools in mainland China. Given the geographical socioeconomic differences

across provinces, it is necessary to examine if the second phase, which involves schools from both inside and outside East China, would be similarly effective.

Resembling other PYD programs, the Tin Ka Ping P.A.T.H.S. Project emphasizes program evaluation. Shek and Sun [12] outlined five key elements to a successful PYD program, including program, process, policy, people, and place (i.e., the 5Ps). Particularly, the element “people” which encompasses program participants and implementers was identified as one of the most decisive factors of all [12]. Thus, utilizing the client satisfaction approach, the present paper is primarily concerned with the program participants’ subjective evaluation of the Tin Ka Ping P.A.T.H.S. Project. The client satisfaction approach, which has been adopted cross-culturally in the field of human services [13, 14], permits researchers to examine the participants’ perceptions of program effectiveness in a cost-effective manner. For instance, Walsh and Lord [15] adopted the Client Satisfaction Questionnaire [16] to gather participants’ views on a social work intervention program. Likewise, utilizing the subjective outcome evaluation approach, Shek and Sun [17] assessed students’ perceived effectiveness of a university subject designed to nurture their leadership skills and intrapersonal development.

Nonetheless, Larson and colleagues [18] noted that students, despite being the target recipients of a program, often had their views overlooked when implementers attempted to evaluate program effectiveness. Such a negligence may stem from the stereotype that adolescents are incapable of expressing dissatisfaction in meaningful ways or that they seldom do so because of early dropout [19]. While findings from subjective outcome evaluation studies regarding the Project P.A.T.H.S. in Hong Kong are well-documented [e.g., 20, 21], we could hardly say the same about the Tin Ka Ping P.A.T.H.S. Project in China. Therefore, it is imperative that we scrutinize the views of the participants on the different aspects of the program such as program content and implementers of the project and how these aspects would interrelate with each another.

In short, utilizing the client satisfaction approach, this study examined the following research questions and hypotheses with reference to the Tin Ka Ping P.A.T.H.S. Project launched in the academic year 2015-2016:

- How do the program participants evaluate the curricula-based program (i.e., Tier 1 Program)? Based on the findings from previous evaluation studies [10], we hypothesized that a high proportion of the program participants would be satisfied with the program (Hypothesis 1). Specifically, with reference to the previous Hong Kong findings that around four-fifths of the respondents were positive about Tier 1 Program, we expected that at least four-fifths of the current respondents would show positive responses.
- How do perceived program content, implementer quality, and program effectiveness inter-relate with one another? Results from the evaluation studies of the Project P.A.T.H.S. in Hong Kong [20, 21] suggested a significant inter-correlation among these three program facets (Hypotheses 2a, 2b, and 2c).
- Are satisfaction ratings different across grades? Based on previous studies [22], it was predicted that the three aspects of client satisfaction would be inter-related (Hypotheses 3a, 3b, and 3c)?

- Are perceived program content and perceived implementer quality predictive of perceived program effectiveness? Based on previous findings [21, 22], we hypothesized that these two factors would predict perceived program effectiveness (Hypotheses 4a and 4b).

OUR STUDY

In the academic year 2015-2016, the curricula-based Tin Ka Ping P.A.T.H.S. Project was implemented in 30 secondary schools in mainland China. Amongst them, eighteen junior secondary schools participated in the current evaluation study. Of these schools, all implemented the program at Secondary 1 (S1 hereafter, equivalent to Grade 7), with three implementing the program also at Secondary 2 (S2 hereafter, equivalent to Grade 8).

To examine the effectiveness of the Tin Ka Ping P.A.T.H.S. Project, students were invited to complete the Subjective Outcome Evaluation Form (the Form A) upon the completion of the program. The program implementers who had attended training workshops over evaluation topics were responsible for data collection. An evaluation manual with standardized instructions on data collection was also distributed to each of the schools concerned. The principles of confidentiality, anonymity and voluntary participation were reiterated upon the administration of the survey. All students provided their consent prior to participation. Altogether 7,289 questionnaires were returned to Research Team. Amongst them, 6,222 were S1 students and 1,067 were S2 students.

Instruments

A well-validated and extensively used [20, 22] instrument (Form A) was adopted to solicit participants' feedback on the program. The Form A contains four parts. Part 1 examined students' overall appraisal of Program content, such as program objectives, design, and interaction among classmates (10 items). Part 2 assessed students' perception of qualities exhibited by the program implementers via ten items measuring aspects like preparation for lessons, degree of involvement, and professionalism. Items of Parts 1 and 2 were rated on a six-point Likert scale with 1 representing "strongly disagree" while 6 representing "strongly agree". The sixteen-item Part 3 assessed students' perceived program effectiveness via a five-point Likert scale (1 = unhelpful; 5 = very helpful). Part 4 contains three additional items measuring the likelihood of the respondents recommending the program to others, participating in a similar program in future, and their overall satisfaction with the program. Additionally, Form A consists of four open-ended questions on students' experience of the program (e.g., aspects of the program worthy of their appreciation). The focus of the present paper is on the quantitative data collected from the program participants.

Data Analyses

The individual data of students were adopted as the units of analysis. Reliability analyses were conducted for the present three subscales (i.e., program content, program implementers, and program effectiveness). Descriptive statistical analyses using the percentage of positive responses to each item were conducted to reveal students' perceptions of the various facets of the program (i.e., Hypothesis 1). To test Hypothesis 2, we examined the associations among the three subscales using the Pearson's correlation tests. Additionally, multivariate analysis of variance (MANOVA) was adopted to test whether there were differences in students' subjective program evaluation across grades (i.e., Hypothesis 3). Finally, Hypothesis 4 was examined via several multiple regression analyses.

FINDINGS

Results on the reliability of Form A are detailed in Table 1. All three parts each recorded excellent internal consistency as evidenced by the high alpha values (ranged from 0.93 to 0.96). The Cronbach's alpha for all three parts combined (i.e., 36 items) was 0.97.

Table 1. Mean, standard deviations, Cronbach's alphas, and mean of inter-item correlations

	Secondary 1		Secondary 2		Overall	
	M (SD)	α (Mean [#])	M (SD)	α (Mean [#])	M (SD)	α (Mean [#])
Program content (10 items)	5.04 (.83)	.92 (.55)	4.99 (.97)	.95 (.66)	5.03 (.85)	.93 (.57)
Program implementers (10 items)	5.26 (.81)	.95 (.66)	5.08 (1.05)	.97 (.77)	5.23 (.85)	.96 (.69)
Program effectiveness (16 items)	4.05 (.81)	.96 (.59)	4.07 (.92)	.98 (.72)	4.06 (.83)	.96 (.61)
Total effectiveness (36 items)	4.67 (.70)	.97 (.46)	4.61 (.67)	.95 (.34)	4.66 (.70)	.97 (.44)

Note. [#] Mean inter-item correlations.

Tables 2 to 5 show the numbers and percentages of students having a positive evaluation on the program. As most of the respondents showed positive evaluation of all facets of the program, there was support for Hypothesis 1. Table 2 shows the descriptive statistics on students' evaluation of the program content. Results showed that an overwhelming proportion of the sample responded positively. For instance, 93.1% thought highly of the curriculum design, 93.8% appreciated the clarity of the curriculum objectives, and 92.7% reported that they generally "liked the curriculum very much".

Table 2. Descriptive statistics of the participants' evaluations on the program content

	Respondents with positive responses (Options 4-6)					
	Secondary 1		Secondary 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
The objectives of the curriculum are very clear.	5834	94.2	969	91.2	6803	93.8
The design of the curriculum is very good.	5782	93.5	964	90.7	6746	93.1
The activities were carefully planned.	5695	92.3	951	89.5	6646	91.9
The classroom atmosphere was very pleasant.	5526	89.5	966	90.9	6492	89.7
There was much peer interaction amongst the students.	5581	90.5	947	89.2	6528	90.3
I participated actively during lessons (including discussions, sharing, games, etc.).	5596	90.6	967	91.1	6563	90.7
I was encouraged to do my best.	5575	90.2	921	86.7	6496	89.7
The learning experience I encountered enhanced my interest towards the lessons.	5659	91.6	944	88.8	6603	91.2
Overall speaking, I have a very positive evaluation of the program.	5583	90.4	940	88.4	6523	90.1
On the whole, I like this curriculum very much.	5756	93.2	955	89.8	6711	92.7

Note. All items were rated on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only the positive responses (Options 4-6) are shown.

Regarding participants' evaluation of the program implementers, over 92% of the respondents rated positively on all the ten items. Some examples included perceived mastery of the curriculum (93.8%), professionalism exhibited (94.0%), preparation for the lessons (94.9%), and overall satisfaction with the implementers (94.9%).

Table 3. Descriptive statistics of the participants' evaluations of the program implementers

	Respondents with positive responses (Options 4-6)					
	Secondary 1		Secondary 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
The instructor(s) had a good mastery of the curriculum.	5839	94.4	951	90.1	6790	93.8
The instructor(s) was well prepared for the lessons.	5894	95.4	967	91.7	6861	94.9
The instructor(s)' teaching skills were good.	5861	94.9	947	89.8	6808	94.2
The instructor(s) showed good professional attitudes.	5830	94.5	961	91.2	6791	94.0
The instructor(s) was very involved.	5864	95.0	962	91.2	6826	94.5
The instructor(s) encouraged students to participate in the activities.	5880	95.4	983	93.3	6863	95.1
The instructor(s) cared for the students.	5851	94.9	942	89.4	6793	94.1
The instructor(s) was ready to offer help to students when needed.	5902	95.7	960	91.1	6862	95.0
The instructor(s) had much interaction with the students.	5792	93.6	936	88.7	6728	92.9
Overall speaking, I have a very positive evaluation of the instructors.	5901	95.5	966	91.6	6867	94.9

Note. All items are rated on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only the positive responses (Options 4-6) are shown.

Table 4 details the descriptive statistics on students' ratings regarding perceived program effectiveness. Over 85% of the respondents showed positive ratings on all the 16 items. For instance, 91.8%, 93.1%, and 92.4% of the students felt that the program had raised their self-confidence, self-awareness, and social competence, respectively. There were 94.4% of them indicating that the program had "enriched my overall development". Table 5 presents students' ratings on the three additional items. Over 90% indicated that they would recommend the program to others (94.5%) and participate in a future similar program (93.2%). Furthermore, 94.3% expressed satisfaction with the program. In short, Hypothesis 1 was supported.

Results of the Pearson correlation analyses showed that the three subscales were significantly and positively correlated with one other. Both program content ($r(6,869) = 0.55$, $p < .001$) and program implementer ($r(6,881) = 0.45$, $p < .001$) were correlated with program effectiveness. The relationship between subscales program content and program implementer was the strongest ($r(6,954) = 0.59$, $p < .001$). Hence, Hypotheses 2a to 2c were supported.

Table 4. Descriptive statistics of the participants' evaluations of the program effectiveness

The extent to which the course (i.e., the program that all students have joined) has helped you:	Respondents with positive responses (Options 3-5)					
	Secondary 1		Secondary 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
It has strengthened my bonding with teachers, classmates and my family.	5496	88.8	933	87.5	6429	88.7
It has strengthened my resilience in adverse conditions.	5610	90.9	984	92.3	6594	91.1
It has enhanced my social competence.	5707	92.5	984	92.3	6691	92.4
It has improved my ability in handling and expressing my emotions.	5675	92.0	978	91.7	6653	92.0
It has enhanced my cognitive competence.	5584	90.6	975	91.5	6559	90.8
My ability to resist harmful influences has been improved.	5778	93.8	971	91.1	6749	93.4
It has strengthened my ability to distinguish between the good and the bad.	5830	94.5	969	90.9	6799	93.9
It has increased my competence in making sensible and wise choices.	5715	92.6	976	91.6	6691	92.4
It has helped me to have life reflections.	5549	89.9	941	88.3	6490	89.7
It has reinforced my self-confidence.	5676	91.9	969	90.9	6645	91.8
It has increased my self-awareness.	5745	93.1	995	93.3	6740	93.1
It has helped me to face the future with a positive attitude.	5715	92.7	993	93.2	6708	92.7
It has helped me to cultivate compassion and care about others.	5647	91.6	970	91.0	6617	91.5
It has encouraged me to care about the community.	5253	85.1	916	85.9	6169	85.2
It has promoted my sense of responsibility in serving the society.	5646	91.4	952	89.3	6598	91.1
It has enriched my overall development.	5846	94.6	995	93.3	6841	94.4

Note. All items are rated on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only the positive responses (Options 3-5) are shown.

Table 5. Summary of the participants' positive perceptions toward other aspects

Items	Secondary 1		Secondary 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
Willingness to suggest other students to participate in the program*	5856	95.1	974	91.3	6830	94.5
Willingness to participate similar programs in future*	5795	94.1	942	88.3	6737	93.2
The extent to which the participants satisfied with the program [^]	5853	95.5	943	88.5	6796	94.4

Note. *A 4-point Likert scale was used (1 = definitely will not, 2 = will not, 3 = will, 4 = definitely will). Only the positive responses (Options 3–4) are shown in this table.

[^]A 6-point Likert scale was used (1 = very dissatisfied, 2 = moderately dissatisfied, 3 = slightly dissatisfied, 4 = satisfied, 5 = moderately satisfied, 6 = very satisfied). Only the positive responses (Options 4–6) are shown.

Table 6. Comparison of participants' subjective evaluation of the program by grade levels

	S1 (<i>N</i> = 5,719)		S2 (<i>N</i> = 1,047)		MANOVA	
	<i>Mean</i>	<i>SD</i>	<i>Mean</i>	<i>SD</i>	<i>F</i> -value	<i>p</i> η^2
1) Program content (10 items)	5.05	0.83	4.99	0.97	4.54* [^]	.001
2) Program implementers (10 items)	5.27	0.80	5.08	1.05	48.12*** [^]	.007
3) Program effectiveness (16 items)	4.06	0.81	4.07	0.92	0.29 [^]	.000
4) Overall score (i.e., total of 1 to 3, 36 items)	4.67	0.70	4.61	0.67	7.70*** [^]	.001

Note. * $p < .05$; ** $p < .01$; *** $p < .001$; [^] Adjusted Bonferroni value = .0125; $p\eta^2$ = partial eta-squared.

Table 6 illustrates the findings of the MANOVA. As expected, results showed that Secondary 1 students had significantly more positive evaluation than did their S2 counterparts on program content ($F = 4.54$, $p = .033$, $p\eta^2 = .001$), program implementers ($F = 48.12$, $p < .001$, $p\eta^2 = .007$), and the overall score ($F = 7.70$, $p = .006$, $p\eta^2 = .001$). However, differences across grade levels were not observed in students' evaluation of program effectiveness ($p > .05$). As such, Hypothesis 3c was not supported.

Lastly, results of the multiple regression analyses (see Table 7) demonstrated that students' evaluations of program content (S1: $\beta = 0.42$, $p < .001$; S2: $\beta = 0.32$, $p < .001$; overall: $\beta = 0.43$, $p < .001$) and program implementers (S1: $\beta = 0.25$, $p < .001$; S2: $\beta = 0.07$, $p = .021$; overall: $\beta = 0.20$, $p < .001$) were significant predictors of their perceived program effectiveness. The overall model explained 32.67% of the variance of perceived program effectiveness. In a nutshell, Hypothesis 4 was confirmed at every grade level and for the entire sample.

Table 7. Multiple regression analyses predicting program effectiveness by program content and implementers

	β^a		<i>F</i>	<i>R</i> ²
	Program content	Program implementers		
Secondary 1	0.42***	0.25***	1837.94***	0.39
Secondary 2	0.32***	0.07*	67.91***	0.12
Overall	0.43***	0.20***	1642.14***	0.33

Note. ^a Standardized Beta coefficients. * $p < .05$ (two-tailed). ** $p < .01$ (two-tailed). *** $p < .001$ (two-tailed).

DISCUSSION

Utilizing the subjective outcome evaluation approach, the present study examined the views of students on the Tin Ka Ping P.A.T.H.S. Project in mainland China. Consistent with the previous findings, results showed that the program was well-received by the majority of program participants. This was evidenced by their positive evaluation of the program content, program implementer, program effectiveness, and their eagerness to recommend this program to others and to participate in a similar program in future. The overwhelmingly positive client satisfaction findings strongly supported Hypothesis 1. The findings also replicated those of Shek et al.'s [10] study covering the first phase of the project launched in East China, thus corroborating the evidence which supports the success of the Tin Ka Ping P.A.T.H.S. Project across China.

Echoing previous research findings from both East China and Hong Kong, significant inter-correlations among the three major program dimensions were observed, giving support to Hypotheses 2a to 2c. While no significant difference in program effectiveness was found across grade levels, Secondary 1 participants had a more positive evaluation of program content, program implementers and they also generally felt more satisfied. Nonetheless, judging by the small effect sizes ($p\eta^2 < 0.01$ for all cases) associated with all the significant grade effects (see Table 6) and taking into account the overall high satisfaction of the entire sample (see Table 1), one could legitimately conclude that both Secondary 1 and 2 participants were indeed very satisfied with the program in terms of its content, implementers, and effectiveness.

Regarding Hypothesis 4, results of multiple regression analyses indicated that both perceptions of program content and implementers were significant predictors of perceived program effectiveness. This finding resonates with Shek and Sun's [12] argument that "people" and "process" are vital to successful PYD programs. Nonetheless, the fact that the present model could only explain 32.67% of the variance implies that additional factors such as "policy" or "place" might be worthy areas of investigation in future evaluation studies.

There are several strengths of the present paper. Supplementing Shek et al.'s [10] pioneer subjective evaluation study of the first phase of the Tin Ka Ping P.A.T.H.S. Project, the present study adds to the scanty empirical work utilizing the client satisfaction approach in the mainland China context. Additionally, a valid and reliable subjective outcome evaluation instrument (i.e., the Form A) was presently adopted to comprehensively examine the different facets of the program. Lastly, via scrutinizing various prospective predictors of perceived program effectiveness and satisfaction, this paper could help researchers build models regarding subjective outcome evaluation in the mainland China context. Particularly, our results suggested that the promotion of perceived effectiveness would hinge on the improvement of the quality of both the program content and its implementers.

There are several limitations of this study. First, as the current analyses were predominantly quantitative, it may be insightful to also examine the open-ended responses to gain an understanding of the feelings of the participants. Second, the present findings may not be representative of the entire school sample ($N = 30$) of the Tin Ka Ping P.A.T.H.S. Project as only eighteen of them took part in the current study. Third, impression management [23] may underlie the present overwhelmingly supportive findings. Students may give desirable ratings as to avoid appearing ungrateful for the implementers' hard work. Nevertheless, this

possibility can be conveniently ruled out because of the anonymous nature of the present survey [24]. Finally, although subjective outcome evaluation has been widely used in the human services domain, it is methodologically superior to incorporate other evaluation methods such as the objective outcome and process evaluation as to reinforce the robustness of the findings. Despite these limitations, the present findings suggest that the Tin Ka Ping P.A.T.H.S. Project launched in the academic year 2015-2016 could be regarded as a success.

ABSTRACT

In this chapter we investigated program implementers' views on the Tin Ka Ping Project P.A.T.H.S. in its first year of implementation in senior high schools in mainland China. After completion of the program, 33 program implementers completed the Subjective Outcome Evaluation Form (Form B). Results showed that over 90% of the implementers had positive views of program content, their self-performance and program effectiveness. In line with previous evaluation studies, perceived worker performance was found to predict perceived program effectiveness. Nevertheless, program content did not predict program effectiveness. Findings of the present study underscore the benefits of implementing the Project P.A.T.H.S. in senior high schools in mainland China.

INTRODUCTION

While adolescence is often regarded as a period with rapid physical development, it is also a transitional period during which adolescents have to go through many challenges [1]. According to World Health Organization (WHO), adolescents may engage in a range of risk behaviors and health issues, including violent behaviors, alcohol and drug abuse, tobacco use, self-harm, and mental health issues [2]. These health compromising behaviors often have negative impacts on the current and future health of adolescents [3]. Based on the statistics of WHO [2], health compromising behaviors among adolescents are prevalent throughout the world.

The problem of health comprising behaviors among adolescents have also drawn public attention in China. In the study of Hesketh, Ding, and Tomkins [4], it was found that nearly 16% of the junior and senior school students responding to the survey were ever smokers. Alcohol use among Chinese adolescents is another serious problem that more attention should be paid. A meta-analytic study of Feng and Newman [5] indicated that over 35% of male students and over 20% of female students in senior high schools had used alcohol in the last 30 days. Regarding illicit drug use, the prevalence rate was about 4% based on a survey of 15 secondary schools in Wuhan [6]. A large-scale study [7] investigated self-harm behaviors among secondary school students in China, and the findings suggested that 17% of the students had injured themselves deliberately in the past 12 months, which was higher than Western countries [7, 8].

Mental health issue is another leading cause of health problem among adolescents [9]. According to a large-scale survey in China, approximately 10% of Chinese school children had suffered from one or more types of psychiatric disorders [10]. Correspondingly, it was estimated that every trained child psychiatrist has to serve more than 40,000 children with behavioral and emotional problems in mainland China [11]. Thus, prevention of health compromising behaviors and mental health problems among children and adolescents is an urgent and important job in mainland China. Unfortunately, there is a lack of prevention programs designed for Chinese adolescents.

Both individual and contextual factors affect adolescent behavior and shape their development [12]. Turbin et al. [13] suggested that adolescent involvement in health-promoting behaviors were more likely to be affected by protective and risk factors in social context (e.g., family and peers), rather than by their individual-level factors. Therefore, providing prevention in the social context would be effective to reduce the risk of adolescent behavior problems and psychiatric disorders. As school is an important place for adolescents to learn knowledge, develop social skills and build social support [1], it would be appropriate to implement prevention programs in school setting, since Chinese adolescents spend more than 8 hours at school each day [14]. Therefore, school-based positive youth development (PYD) programs for the general adolescent population is a promising approach to promote holistic development in adolescents.

With respect to the above-mentioned issues, a PYD program entitled “P.A.T.H.S. to Adulthood: A Jockey Club Youth Enhancement Scheme” was initiated in Hong Kong in the 2005-2006 academic year and then piloted in mainland China from 2007-2008 academic year to 2009-2010 academic year [15, 16]. The initial version of the Project P.A.T.H.S. was designed by the first author and his collaborators from five universities in Hong Kong and

funded by The Hong Kong Jockey Club Charities Trust. Two tiers of programs were included in the project to help adolescents with different levels of need. The Tier 1 Program provides a series of curricula-based training programs to the general adolescent population in junior secondary schools that students participate in 10 to 20 hours of training on 15 PYD constructs in each school year, whereas the Tier 2 Program is designed for one-fifth of the students who have greater psychosocial needs [17].

Because of the prominent success in the implementation of the project in Hong Kong, a pilot project was funded by Tin Ka Ping Foundation and implemented in four schools in mainland China (including Shanghai, Suzhou, Changzhou and Yangzhou) in 2011-2014. As a transplant of the Project P.A.T.H.S. (i.e., Tin Ka Ping P.A.T.H.S. Project), the pilot project had very good performance. Thus, a second phase of the project was funded to fully implement the project from 2014-2015 academic year [18, 19]. In the academic year of 2015-2016, a total of 30 secondary schools joined the project and the curriculum for senior high schools was also developed. To facilitate program implementation, a series of in-service training programs were provided to school teachers and social workers from participating schools.

Subjective outcome evaluation is a useful approach to gather feedback from stakeholders of programs (e.g., program participants and implementers) and assess their satisfaction. The views of the stakeholders can provide ideas to improve program content and process, which have implications to the application of the program in the general population. Previous evaluation studies using subjective outcome evaluation approach showed that both students and school teachers held very positive views toward the project, which echoes the results of qualitative evaluation and objective outcome evaluation of the project [18-21]. However, the perceptions of program implementers from senior schools are still unknown.

As implementers are an indispensable part of a program, the feedback from these well trained professionals in the field of positive adolescent development could be very helpful to improve program content. Moreover, their first-hand experience of delivering program to students would provide practical data to review the program, as they would not adapt materials which are not fit in their situation [22]. Implementers could review their own practice when they are doing evaluation, and such evaluation could provide them with a sense of respect and fairness [23].

The purpose of the present study was to examine program implementers' perceptions toward the project implemented in senior high schools in China. Subjective outcome evaluation approach was used to collect feedback of implementers who delivered the senior curriculum. As there are very few programs focusing on promoting holistic and positive development for students of senior high schools in mainland China, the evaluation study can provide good insight into the efficacy of the Project P.A.T.H.S. and the factors associated with program success. Three sets of research questions and hypotheses were examined in the present study:

- What are program implementers' perceptions of the project implemented in senior high school? Would the findings be consistent with the findings of previous evaluation studies of programs conducted in junior secondary school? Based on previous studies, it was expected that a majority of the respondents (at least 80%) would have positive view of the program (Hypothesis 1).

- Are there any significant inter-relationships among the three aspects of subjective outcome evaluation? Based on the results of previous findings, we hypothesized that perceived program effectiveness would be significantly associated with program content (Hypothesis 2a) and perceived worker performance (Hypothesis 2b).
- What are the predictors of perceived effectiveness of the program? Based on the findings of previous study, we hypothesized that program content and perceived worker performance would predict the effectiveness of the project (Hypothesis 3a and 3b, respectively).

OUR STUDY

In the academic year of 2015-2016, the Tin Ka Ping P.A.T.H.S. Project was implemented in 30 junior and/or senior high schools in mainland China. To explore program implementers' viewpoints toward the program and their self-performance, and to evaluate program effectiveness, school teachers who taught the senior school programs were invited to complete the Subjective Outcome Evaluation Form for Instructors (Form B) after program curriculum was finished.

A total of 33 implementers from four senior secondary schools in mainland China, with a range from five to twelve teachers in each school, have submitted the Form B after the completion of program. To ensure survey response quality, an evaluation manual with a clear guideline on the completion of Form B was provided to the teachers before they started to fill in the evaluation form. Relevant training on evaluation was also included in different training workshops.

Instruments

The Subjective Outcome Evaluation Form for Instructors (Form B) has been widely applied over the past decade and evaluation studies of the project demonstrate that Form B is a valid and reliable measure gathering feedback from program implementers of the project [24]. Form B consists of both open-ended questions that provide qualitative data and quantitative scales. As shown in Table 1, the three subscales used in Form B have demonstrated very good internal consistency with Cronbach's α s above .90. Due to space limitation, the present study focused on the quantitative data collected from the following items/subscales:

- A 6-point Likert scale assessing implementers' perceptions of program content (10 items);
- A 6-point Likert scale assessing implementers' perceptions of self-performance (10 items);
- A 5-point Likert scale assessing implementers' perceptions of program effectiveness (16 items);
- One item assessing the degree to which implementers would recommend other students to join the program;

- One item assessing the degree to which teachers would teach similar curriculum in the future;
- One item assessing implementers' view toward their professional growth through the program.

Table 1. Mean, standard deviations, Cronbach's alphas, and mean of inter-item correlations

	M	SD	α	Mean [#]
Program content (10 items)	5.17	0.87	.97	.75
Program implementers (10 items)	5.08	0.89	.97	.78
Program effectiveness (16 items)	4.10	0.77	.98	.72
Total effectiveness (36 items)	4.66	0.78	.99	.66

Note: [#] Mean inter-item correlations.

Data Analyses

First, reliability analyses were conducted to examine the internal consistency of the three subscales in Form B and the inter-item correlations among them. Second, descriptive analyses were performed to compute the percentage of positive responses of implementers' perception of program components (program content and implementers' self-performance) and program effectiveness. Third, to examine the correlations between program content, implementers' self-performance and program effectiveness, Pearson correlation analysis was performed. Finally, multiple regression analysis was conducted to test the potential predictors of perceived program effectiveness, including program content and implementers' perceived self-performance. All statistical analysis was performed using SPSS 23.0.

FINDINGS

Program implementers' perceptions of program content, self-performance and program effectiveness are shown in Tables 2-4, respectively. Generally speaking, their views toward the aspects measured in Form B were very positive. Over 96% of the respondents had positive responses on eight out of ten items regarding program content, such as design of the program, program activities, atmosphere in the classroom, student classroom participation, theoretical support and teacher's interest toward the curriculum. Over 90% of the respondents agreed that "the objectives of the curriculum are very clear," and "there was much peer interaction amongst the students." Overall speaking, the respondents perceived positive features of program content (see Table 2). Similarly, the majority of the respondents also had positive perceptions toward their own performance. Seven out of ten questions regarding implementers' perceived self-performance received positive responses from over 96% of the respondents (see Table 3).

Table 2. Summary of the program implementers' perceptions toward the program content

		N	Mean	SD	Respondents with positive responses (Options 4-6)	
					n	%
1.	The objectives of the curriculum are very clear.	32	5.22	1.04	30	93.8
2.	The design of the curriculum is very good.	32	5.06	0.91	31	96.9
3.	The activities were carefully planned.	32	5.19	0.93	31	96.9
4.	The classroom atmosphere was very pleasant.	32	5.19	1.00	31	96.9
5.	There was much peer interaction amongst the students.	32	5.19	1.12	30	93.8
6.	Students participated actively during lessons (including discussions, sharing, games, etc.)	32	5.16	0.95	31	96.9
7.	The program has a strong and sound theoretical support.	32	4.88	0.98	31	96.9
8.	The teaching experience I encountered enhanced my interest towards the lessons.	32	5.16	0.99	31	96.9
9.	Overall speaking, I have very positive evaluation of the program.	32	5.25	1.02	31	96.9
10.	On the whole, students like this curriculum very much.	32	5.41	0.98	31	96.9

Note: All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Table 3. Summary of the program implementers' perceptions toward their own performance

		N	Mean	SD	Respondents with positive responses (Options 4-6)	
					n	%
1.	I have a good mastery of the curriculum	32	4.88	1.07	29	90.6
2.	I prepared well for the lessons.	32	4.94	1.05	30	93.8
3.	My teaching skills were good.	32	4.75	0.98	30	93.8
4.	I have good professional attitudes.	32	5.00	1.02	31	96.9
5.	I was very involved.	32	5.06	0.95	31	96.9
6.	I gained a lot during the course of instruction.	32	5.09	1.00	31	96.9
7.	I cared for the students.	32	5.28	0.99	31	96.9
8.	I was ready to offer help to students when needed.	32	5.41	0.98	31	96.9
9.	I had much interaction with the students.	32	5.19	0.97	31	96.9
10.	Overall speaking, I have very positive evaluation of myself as an instructor.	32	5.19	0.93	31	96.9

Note: All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Results in Table 4 indicated that there were a number of perceived benefits of the project. Over 96% of the respondents agreed that the program could strength students' bonding with their families, teachers and classmates, enhance students' resilience and their competence in regard to social skills, emotion capital and cognitive functioning, and increase students' self-awareness and self-confidence, etc. The great majority (97%) of the respondents agreed that the program enriched students' overall development. From the program implementers' subjective views toward other aspects of the program, all of them (100%) would suggest the students who have similar needs join the program. In addition, 97% of the respondents had intention to teach similar programs again in the future, and over 93% of respondents

perceived the program as helpful in their professional growth (Table 5). In short, the findings supported Hypothesis 1.

Table 4. Summary of the program implementers' perceptions toward the program effectiveness

The extent to which the Tier 1 Program (i.e., the program in which all students have joined) has helped your students:		N	Mean	SD	Respondents with positive responses (Options 3-5)	
					n	%
1.	It has strengthened students' bonding with teachers, classmates and their families.	33	4.18	0.88	32	97.0
2.	It has strengthened students' resilience in adverse conditions.	33	4.03	0.85	32	97.0
3.	It has enhanced students' social competence.	33	4.30	0.85	32	97.0
4.	It has improved students' ability in handling and expressing emotions.	33	4.39	0.83	32	97.0
5.	It has enhanced students' cognitive competence.	33	3.97	0.88	32	97.0
6.	Students' ability to resist harmful influences has been improved.	33	4.03	0.95	31	93.9
7.	It has strengthened students' ability to distinguish between the good and the bad.	33	4.09	0.95	31	93.9
8.	It has increased students' competence in making sensible and wise choices.	33	3.91	0.91	31	93.9
9.	It has helped students to have life reflections.	33	3.94	0.90	32	97.0
10.	It has reinforced students' self-confidence.	32	4.19	0.78	31	96.9
11.	It has increased students' self-awareness.	32	4.31	0.86	31	96.9
12.	It has helped students to face the future with a positive attitude.	33	4.30	0.81	32	97.0
13.	It has helped students to cultivate compassion and care about others.	33	4.06	0.90	32	97.0
14.	It has encouraged students to care about the community.	33	3.55	1.00	30	90.9
15.	It has promoted students' sense of responsibility in serving the society.	33	3.94	1.06	30	90.9
16.	It has enriched the overall development of the students.	33	4.30	0.85	32	97.0

Note: All items are on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3-5) are shown in the table.

Table 5. Other aspects of subjective outcome evaluation based on the program implementers' perceptions

		N	Mean	SD	Respondents with positive responses	
					n	%
Q3	If you have a student/client whose needs and conditions are similar to those of your students who have joined the program, will you suggest him/her to participate in this program?	33	3.58	0.50	33	100
Q4	If there is a chance, will you teach similar programs again in the future?	33	3.58	0.56	32	97.0
Q5	Do you think the implementation of the program has helped you in your professional growth (e.g., enhancement of your skills)?	32	4.28	0.89	30	93.8

Note: For Q3 & Q4, the item is on a 4-point Likert scale with 1 = definitely will not teach, 2 = will not teach, 3 = will teach, 4 = definitely will teach. Only respondents with positive responses (Options 3-4) are shown in the table. For Q5, the item is on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3-5) are shown in the table.

The results of correlation analyses showed that program content, program implementers' perceived worker performance and program effectiveness were significantly associated with each other (r s ranged from .73 to .92, p s < .01; see Table 6). The findings gave support to Hypotheses 2a and 2b. Table 7 presents the results of multiple regression analysis. Consistent with Hypothesis 3b, the overall perception of program implementers' self-performance predicted program effectiveness ($\beta = .65$, $p < .05$). However, Hypothesis 3a was rejected, as program content was not a significant predictor of the benefits of the program based on the data of the present study. This model explained 59% of the variance of program effectiveness.

Table 6. Correlation coefficients on the relationship between program components and program effectiveness

Variable	1	2	3
1. Program content (10 items)	—	—	—
2. Program implementers (10 items)	.92**	—	—
3. Program effectiveness	.73**	.77**	—

** $p < .01$.

Table 7. Multiple regression analyses predicting program effectiveness

	Predictors		Model	
	Program content	Program implementers		
	β^a	β^a	R	R^2
Program effectiveness	.12	.65*	.77	.59

Note: Missing values were replaced with mean ; ^a Standardized coefficients; * $p < .05$.

DISCUSSION

To promote students' whole person development in senior high schools, innovative units and topics based on PYD constructs were developed and incorporated into the senior curriculum of P.A.T.H.S. programs in mainland China. This initiative is groundbreaking in different Chinese communities. Utilizing the subjective outcome evaluation approach, this study examined stakeholder satisfaction of program components (quality of content and implementers) and program effectiveness based on the perceptions of program implementers who taught the senior curriculum of Tier 1 Program in the academic year of 2015-2016. Generally speaking, the great majority of the implementers who responded to the survey were satisfied with the project and recognized its positive influences on adolescent development. The present study replicated the previous evaluation findings in junior secondary schools [24, 25].

As the first subjective evaluation regarding implementers' views of senior school program, several observations can be highlighted. First, approximately 97% of the respondents held positive views toward program content, self-performance and benefits of the program. Second, relatively fewer teachers (90.9%) agreed that the program promoted students' sense of social responsibility and encouraged them to care more about community development, which was consistent with previous evaluation findings [25, 26]. One explanation is that community involvement is more difficult to observe, as activities in the project are mainly conducted within school settings. However, the findings can still be regarded as very positive. Third, this study replicated the relationships among the three aspects of subjective outcome evaluation that both program content and implementers' self-performance had strong and positive relationships with program effectiveness. Fourth, the performance of program implementers was identified as a significant predictor of positive effects of the program. However, in contrast to previous studies based on student participants, program effectiveness was not statistically significant.

There are several reasons why the project was successful and positive feedbacks were received. First, the remarkable success of the junior school programs in Hong Kong and mainland China provides experience and materials for implementing similar programs in senior secondary schools. Second, as implementers in the present study were school teachers who aspired to pass on their knowledge and positive attitude toward life to students, they would have a higher motivation to deliver the program. Third, teaching and learning behavior expected in PYD programs is different from traditional way of education in China. Because different teaching and learning methods are used in the programs, including group discussion, role play, self-reflections, and multimedia teaching, students can be more actively involved [17]. Fourth, in-service training programs for teachers can help strengthen their understanding of PYD constructs and program content [15]. Implementers would be more likely to evaluate their performance and the program positively if they observe that students have positive changes after attending the program [27].

The findings in the present study would be a good reference for similar research and programs in the future, which provide a synthesis of stakeholder satisfaction on program implementation and effectiveness. It is important to collect the views of program implementers, since they play the role of a medium between program participants and program operation. As an indispensable factor contributing to an effective program in the 5P

model (i.e., policy, program, place, process and people), program implementers have crucial influence on program effectiveness [28]. In future studies, researchers may investigate if implementers' perceptions are consistent with students' subjective and objective evaluation of the program.

The present study has several limitations. First, because this is an initial evaluation study of the senior school program of Project P.A.T.H.S., the sample size is relatively small. Hence, the findings could only represent the views of teachers in a few project schools. Second, as few schools joined the evaluation, it is unclear if implementers teaching different grades have different views on the program. Third, only quantitative data were reported in this study. Obviously, a more comprehensive picture of implementers' feedback on the program requires both quantitative and qualitative evaluation. Therefore, it is helpful to include more teachers using different evaluation methods in future evaluation studies.

Despite these limitations, the results of this study demonstrated that the Tier 1 Program of the Tin Ka Ping P.A.T.H.S. Project in mainland senior high schools was positively evaluated by program implementers and they had positive effects on adolescent development, which is pioneer in the Chinese contexts. In view of the limited international and local research on positive youth development programs in China, the present study provides an insight into the initial application of Tin Ka Ping P.A.T.H.S. Project among senior high school students and teachers.

ABSTRACT

In this chapter we investigated the participants' perceptions of a training program conducted in Tin Ka Ping P.A.T.H.S. Project in China using the subjective outcome evaluation approach. The participants (N = 151) completed an evaluation form at the end of the training program. Results showed that a very high proportion of the participants were satisfied with the training program in terms of program content, instructors, administrative arrangements, and their own performance. Several significant predictors of effectiveness of the training program were identified, including program quality, instructor quality, administrative arrangement, and participants' perceived self-performance. Perceived program quality also predicted overall satisfaction of the participants. Together with previous evaluation findings, the present study suggests that the Tin Ka Ping P.A.T.H.S. Project training program was effective and well received by colleagues in mainland China.

INTRODUCTION

With the implementation of one-child policy from 1978 to 2015 and the expanding urban-rural gap in China, adolescent developmental problems have been a critical issue for psychologists, educators, scholars, and the Government in China. Research on the mental health condition of only-child expanded at a remarkable rate in past 10 years. For instance, Hesketh and his colleagues [1] estimated that the suicide rate of adolescents in China was around three times the global average. Xing et al. [2] reported that Chinese adolescents with suicide attempts usually have family problems, such as improper parental rearing behavior, parental divorce, and parental gambling problem. Moreover, it is estimated that over 24 million (14.1%) adolescents in urban cities displayed symptoms of internet addiction [3]. In addition, it also revealed that the adolescents from less developed areas in China have higher prevalence rates of youth internet addiction problem (14.8%) than those from high developed cities (8.4%) [3].

In view of the above observations, it is advocated that effective positive youth development (PYD) programs to strengthen the psychosocial competencies of adolescents are in urgent need in China. The PYD approach emphasizes that “problem-free is not fully prepared” and utilizes the ecological (person-in-environment) and strengths-based principles [4]. It focuses on preventing a wide range of adolescent developmental problems and needs, instead of merely preventing a single adolescent problem.

With particular reference to Hong Kong, adolescents are also facing different types of risk behavior such as substance abuse, materialism, suicide, and bullying [5]. As such, a PYD program entitled “P.A.T.H.S. to Adulthood: A Jockey Club Youth Enhancement Scheme” funded by Hong Kong Jockey Club Charities Trust was launched in 2004. The project comprised of two tiers programs. While the Tier 1 Program was a universal curriculum-based program based on 15 PYD elements identified in the effective programs, such as bonding, social competence, cognitive competence, and behavioral competence [6], the Tier 2 Program was developed for participants who were identified with greater psychosocial needs and tailor-made special programs were constructed. Multiple evaluation studies revealed that project in Hong Kong has received notable success in promoting holistic youth development and preventing problem behavior among junior secondary school students [7-10].

Given the overwhelming success of project in Hong Kong, it is important to ask whether the program can promote the holistic development of adolescents in other Chinese communities. With the financial support from Tin Ka Ping Foundation, a project entitled “Tin Ka Ping P.A.T.H.S. Project” was implemented in four schools in East China, including Shanghai, Suzhou, Changzhou, and Yangzhou from 2011 to 2014, with good outcomes based on subjective and objective outcome evaluation [11, 12].

Despite the encouraging evaluation findings reported in four East China secondary schools [11, 12], we need to further understand the applicability of the program in other parts of China. Hence, a second phase of the Project P.A.T.H.S. designed for the junior secondary school students was implemented in more than 30 secondary schools in mainland China from the 2014-2015 academic year, with the first year as the preparatory year of a full-implementation stage.

Unlike other traditional youth prevention programs, this project emphasizes systematic training through experiential and reflective learning approaches. With respect to the training

programs for the potential implementers of the project in Hong Kong, all potential implementers were expected to actively participate in the training process as students [13]. Participants were given opportunities to reflect on their own values, teaching methods, and attitude towards adolescent development [14]. Such an emphasis was also adopted in the training programs in mainland China. Specifically, four junior form training sessions were offered in Shanghai, Suzhou, and Chongqing in the preparatory year (2014-2015 academic year).

From 2015-2016 to 2016-2017 academic year, the program was launched in over 30 secondary schools in China. In the 2015-2016 academic year, three training workshops targeting potential implementers of the junior and senior secondary programs were held in Zhaoqing, Shaoguan (in Guangdong province), and Changchun (in Jilin province), respectively. The evaluation findings of the training held in Zhaoqing and Shaoguan have been documented [15, 16].

In this chapter, perceptions of the participants joining the training conducted in Changchun were examined. As the training was conducted during the summer holiday, the research team extended the training period from 3 days to 4 days. Therefore, more lesson demonstrations and in-depth sharing sessions from project schools were included. The contents of the third training workshop in Changchun are shown in the Appendix. There were several objectives of this training program: (a) to understand the concepts and rationale of PYD; (b) to understand the features of adolescent development and to develop positive attitudes towards adolescents; (c) to comprehend the rationales, design, implementation, and evaluation of the project; (d) to understand the contents and activities developed for the project; (e) to encourage participants to review and obtain appropriate attitude, knowledge, and teaching skills to facilitate program implementation; and (f) to develop a self-help network among the participants.

Although the importance of prevention programs and PYD programs for adolescents have been highlighted in previous studies, the significance of training programs for implementers tends to be overlooked. Clarke [17] believed that training program should be treated as a key strategy to help trainees familiarize with the program philosophy and content, and strengthen their enthusiasm and support for the program. Fullan [18] also pointed out that the impact of shared meaning and collaboration from the implementers would determine the effectiveness of educational program. Shek and Sun [19] listed five key factors contributing to the success of the PYD program, including program, process, policy, people, and place (i.e., 5 P's). Amongst these factors, "people," which included both program participants and implementers, was identified as the most influential factor affecting the effectiveness of the project [19]. As such, providing systematic and on-site training for the potential program implementers should be taken into account in program delivery. Moreover, since there are very few PYD programs in China, it is important to provide comprehensive support and resources to the project schools and implementers through all-rounded in-service training.

In addition, it is advocated that training evaluation is necessary in every training program. Training evaluation refers to "the process of determining the merit, worth, and value of things, or the product of that process" [20]. In other words, it is a methodological approach for measuring a training program's achievement with regard to program design and content, and changes in trainees. Kirkpatrick's [21] four dimensional training evaluation model (i.e., reactions, learning, behavior, and results) is widely used for understanding the purpose of in-service training evaluation. Training evaluation results can give scientific evidence to explain

how the objectives of training program, content, and methods achieve the expected outcomes or benefits in the training [22]. Furthermore, program developer can identify successful factors through evaluation and then improve program design and implementation in the future.

To date, several training evaluation studies of the project based on subjective outcome evaluation strategy have been conducted in Hong Kong [23-26]. Comparatively speaking, there are still very few training evaluations conducted in Chinese communities. As reviewed by Yang and Guo [27], there were only 86 Chinese studies related to teacher training evaluations published in the last decade in 11 major Chinese or international databases. Besides, most of these studies simply focused on conceptual issues rather than investigating the efficacy of training programs. Most importantly, as the Project P.A.T.H.S. has moved to a full implementation stage, it is worth exploring the influence of its training program on potential implementers and collecting their feedbacks for further improvement.

The current study attempted to examine the effectiveness of the Project P.A.T.H.S. training program conducted in Changchun in August 2016. Similar to other training evaluation studies reported previously [15, 16], there are three research objectives of this paper: 1) to explore potential implementers' viewpoints towards the training program in the areas of training content, instructors' quality, self-performance, and administrative arrangements; 2) to examine the predictors of perceived benefits through the training program from the perspective of the participants; 3) to investigate the predictors of overall satisfaction with the training program amongst the participants.

OUR STUDY

In the academic year of 2015/2016, the third training workshop of the Tin Ka Ping P.A.T.H.S. Project was held in Changchun, China. There were altogether 208 teachers from 35 junior and/or senior secondary schools registering to attend this 4-day workshop.

During the last session of the workshop in Day 4, the participants reflected on their gains through the training, and they were invited to complete an anonymous questionnaire regarding their evaluation on this training workshop. Because of transportation constraints, some participants had to leave earlier upon the completion of the training. Finally, a total of 151 questionnaires were collected, including 70 (46.4%) questionnaires completed by junior secondary school teachers and 81 (53.6%) completed by senior secondary school teachers. Overall speaking, there were more female teachers ($N = 103$, 68.2%) than male teachers ($N = 48$, 31.8%) completing the evaluation after the training. Among all the respondents, 62.9% ($N = 95$) had over 10 years of teaching experience. In addition, the mean years of working experience of the respondents was 12.6 ($SD = 8.42$).

Instruments

The participants' perceptions of the training workshop were measured utilizing the Subjective Outcome Evaluation Questionnaire developed by Shek and his colleagues [24].

The evaluation questionnaire consists of 33 items, including four subscales measured by 31 closed-ended questions and two open-ended questions.

Regarding the four subscales, each respondent is asked to rate the items on a 5-point Likert scale with responses ranging from “strongly disagree” to “strongly agree.” The first subscale, comprising 16 items, measures participants’ overall view of the program training content, including the perceived benefits of the program (9 items), perceived program quality (5 items) and satisfaction degree of participants (2 items). The second subscale investigates participants’ perceptions of the instructors with 5 items. The third subscale, consisting of 4 items, assesses participants’ reflections on their own performance. The fourth subscale focuses on participants’ evaluations of the administrative arrangements of the training. The two open-ended questions examine participants’ most appreciated part of the training and their suggestion for the workshop.

The quantitative part of the questionnaire has demonstrated excellent internal consistency (Cronbach’s $\alpha > .9$) in previous studies evaluating the training programs in Hong Kong [25, 26]. The current study focused on the participants’ perceptions by analyzing the data from the four subscales.

FINDINGS

Table 1 shows that the reliability measures for the total scale (Cronbach’s $\alpha = .95$) and subscales of the Subjective Outcome Evaluation Questionnaire (Cronbach’s alpha ranged from .66 to .93) had good reliability status. Although the alpha value for the overall satisfaction subscale was not high (Cronbach’s $\alpha = .66$), it can be regarded as reasonable because there are only two items in this subscale.

Participants’ perceptions of the program content, program instructors, their own performance and the administrative arrangements of the training are shown in Tables 2-5 respectively. The numbers and percentages of positive responses (scores equal to or above 4) to each item and subscale are presented. In general, the majority (over 80%) of the participants held a positive view regarding program benefits, program quality, program instructors and the administrative arrangements. And taken as a whole, nearly 90% of the participants were satisfied with the workshop. However, relatively fewer participants (74.7%) expressed positive views about their self-performance, although the value was respectable.

Table 1. Means, standard deviations, Cronbach’s alphas, and mean of inter-item correlations

Subjective Outcome Evaluation Scales	<i>M</i>	<i>SD</i>	Cronbach’s α	Mean Inter-item correlation
Perception of the training program (16 items)	4.42	0.43	.93	.47
Perceived benefits (9 items)	4.44	0.44	.89	.49
Program quality (5 items)	4.39	0.48	.81	.47
Overall satisfaction (2 items)	4.33	0.54	.66	.49
Perception of program instructor (5 items)	4.49	0.46	.85	.54
Perception of self-performance (4 items)	4.15	0.53	.81	.52
Perception of administrative arrangements (6 items)	4.44	0.49	.91	.65
Total scale (31 items)	4.41	0.39	.95	.40

Table 2. Summary of the positive views (options 4-5) of the participants towards the training program

Perceptions of the program	N	Agree (4)		Strongly Agree (5)		Positive Response (Options 4-5)		M	SD
		n	%	n	%	n	%		
Perceived benefits ^a									
1. It has strengthened my understanding of the nature of adolescent development.	146					127	87.0	4.44	0.44
2. It has helped me to cultivate positive attitude to adolescent development.	147	71	48.3	71	48.3	142	96.6	4.45	0.56
3. It has strengthened my understanding of positive youth development, including its concept, design and research.	147	55	37.4	90	61.2	145	98.6	4.6	0.52
4. It has helped me to understand the Project P.A.T.H.S., including its basic philosophy, design, implementation, and evaluation.	147	60	40.8	80	54.4	140	95.2	4.5	0.59
5. It has strengthened me to understand the content of the Project P.A.T.H.S..	147	62	42.2	74	50.3	136	92.5	4.43	0.63
6. It has helped me to acquire the attitude, knowledge and skills that are conducive to the successful implementation of the Project P.A.T.H.S..	147	68	46.2	72	49.0	140	95.2	4.44	0.59
7. It has helped me to establish self-help support network and share teaching experiences among the program participants.	147	76	51.7	57	38.8	133	90.5	4.29	0.65
8. It has promoted self-reflection.	147	58	39.5	71	48.3	129	87.8	4.36	0.69
9. It has helped me to recognize factors affecting teaching.	146	65	44.2	78	53.1	143	97.3	4.5	0.55
Program quality ^a	145	71	48.6	67	45.9	138	94.5	4.4	0.59
1. The training methods and activities are appropriate (e.g. lecture, games, group discussion).	145					121	83.4	4.39	0.48
2. Training time is appropriate.	147	64	43.8	80	54.8	144	98.6	4.53	0.53
3. It has met my expectation.	147	74	50.3	45	30.6	119	80.9	4.08	0.77
4. There was much peer interaction amongst participants.	147	73	49.7	54	36.7	127	86.4	4.23	0.67
5. Instructor(s) encouraged participants to do the best.	146	59	40.4	81	55.5	140	95.9	4.51	0.60
Overall satisfaction ^a	147	53	36.1	88	59.9	141	96.0	4.55	0.60
1. Overall speaking, I am satisfied with the training program.	145					130	89.7	4.33	0.54
2. I think participants are satisfied with the training program.	147	73	49.7	67	45.5	140	95.2	4.41	0.58
Perceptions of the program (whole scale) ^a	145	72	49.7	55	37.9	127	87.6	4.25	0.68
	143					116	81.1	4.42	0.43

Note: ^a Scores equal to or higher than 4 were treated as positive views.

Table 5. Summary of the positive views (options 4-5) of participants towards administrative arrangements

Perceptions of the administrative arrangements		N	Satisfied (4)		Very Satisfied (5)		Positive Response (Options 4-5)		M	SD
			n	%	n	%	n	%		
1.	Information obtained before attending the workshop.	151	76	50.3	55	36.4	131	86.7	4.23	0.69
2.	Workshop assigned.	150	74	49.3	64	42.7	138	92.0	4.35	0.62
3.	Location of the workshop.	151	75	49.7	71	47.0	146	97.7	4.44	0.56
4.	Reception provided by training team (e.g. transportation arrangement, refreshments).	151	59	39.1	88	58.3	147	97.4	4.56	0.55
5.	Facilities of the venue.	151	64	42.4	82	54.3	146	96.7	4.51	0.56
6.	Overall speaking, I am satisfied with the administrative arrangement.	151	61	40.4	89	58.9	150	99.3	4.58	0.51
Total scale ^a		150					130	86.7	4.44	0.49

Note: ^a Scores equal to or higher than 4 were treated as positive views.

Regarding perceived benefits, more than 90% of the respondents agreed or strongly agreed that they benefitted from the training, including a better understanding of adolescent development (96.6%) and positive youth development (95.2%), cultivation of positive attitude to adolescent development (98.6%), self-reflection (97.3%), and recognition of factors affecting teaching (94.5%). In addition, through the workshop, the teachers were more familiar with the project (92.5%), understood the content of the Tier 1 Program (95.2%), and acquired knowledge and skills implementing the program (90.5%). Nearly 90% of the respondents agreed that they established a self-help support network in the training.

The teachers in the training were also satisfied with the program quality. Almost all of them (98.6%) agreed that the training methods and activities were appropriate. They also held a positive view about peer interaction amongst teachers during the training (95.9%). Most participants had positive evaluation of program instructors. They agreed that the instructors were a professional team with good mastery of the curriculum (98%), clear understanding of the needs of the participants (87.7%), profession attitude (98.6%) and good teaching skills (88.5%). The participants also showed positive response toward the administrative arrangements of the program. After the training, 96% of the teachers expressed their willingness to use the theories and skills learnt through this training workshop.

To investigate whether there were differences between junior and senior secondary school teachers regarding their perceptions of the training workshop, a MANOVA analysis was performed. As demonstrated in Table 6, based on the omnibus F test, no statistically significant difference was found between the junior form and senior form programs in terms of the overall perception of the training ($F = 1.54, p > .05$).

Table 6. The comparison between junior and senior secondary school participants on the perceptions of the training program

Subjective Outcome Evaluation Scales	Senior			Junior			F
	N	M	SD	N	M	SD	
Program content (16 items)	66	4.48	.40	77	4.36	.45	2.78
Perceived benefits (9 items)	66	4.51	.42	80	4.37	.45	3.81
Program quality (5 items)	67	4.45	.42	78	4.33	.52	2.29
Overall satisfaction (2 items)	67	4.42	.54	78	4.26	.54	2.98
Program instructor (5 items)	67	4.51	.44	80	4.47	.48	.36
Perceived self-performance (4 items)	69	4.30	.49	81	4.02	.54	11.16**
Administrative arrangements (6 items)	70	4.52	.45	80	4.37	.51	3.5
Total scale (31 items)	65	4.47	.36	76	4.34	.40	3.6

Note: ** $p < .01$.

Table 7. Pearson correlations among the key evaluation components

Variable	1	2	3	4	5	6
Perceived benefits (9 items)	-					
Perceived program quality (5 items)	.82***	-				
Instructor quality (5 items)	.64***	.60***	-			
Self-performance (4 items)	.54***	.50***	.38***	-		
Administrative arrangements (6 items)	.65***	.61***	.51***	.51***	-	
Overall satisfaction (2 items)	.69***	.76***	.50***	.44***	.58***	-

Note: *** $p < .001$.

The correlations among participants' perceptions of perceived benefits, program quality, instructor quality, self-performance, administrative arrangements, and overall satisfaction were examined using Pearson correlation analyses. The findings shown in Table 7 demonstrate that all related variables were significantly and positively associated to different extent (r s ranged from .38 to .82, $ps < .001$). In addition, a strong relationship was observed between perceived benefits and program quality ($r = .82$, $p < .001$).

Table 8. Multiple regression analyses predicting perceived benefits and overall satisfaction

Predictors	Perceived Benefits				Overall Satisfaction			
	<i>B</i>	<i>SE</i>	β	R^2	<i>B</i>	<i>SE</i>	β	R^2
Perceived program quality	0.53	.06	.57***	.74	0.64	.11	.55***	.60
Instructor quality	0.15	.06	.15**		0.03	.09	.023	
Self-performance	0.10	.04	.12*		0.04	.07	.03	
Administrative arrangements	0.15	.06	.16**		.16	.09	.14	
Perceived benefits					.13	.13	.11	

Note: * $p < .05$; ** $p < .01$; *** $p < .001$.

To investigate the predictors of perceived benefits of the participants and factors associated with their overall satisfaction, two multiple regression analyses were performed. The findings in Table 8 show that program quality ($\beta = .57$, $p < .001$), instructor quality ($\beta = .15$, $p < .01$), self-performance ($\beta = .12$, $p < .05$) and administrative arrangements ($\beta = .16$, $p < .01$) could significantly predict the perceived effect of the program, with program quality as the strongest predictor of perceived benefits. Program quality also predicted overall satisfaction of the participants ($\beta = .55$, $p < .001$). However, other factors, including instructor quality, self-performance, administrative arrangements and perceived benefits did not significantly contribute to the overall satisfaction.

DISCUSSION

To promote the holistic and positive development in Chinese adolescents, the Project P.A.T.H.S. was transplanted to mainland China and has been implemented in over 30 secondary schools across the country [12, 29]. Obviously, in-service training offered to school teachers is regarded as an indispensable part of this large scale implementation, because teachers usually play a crucial role in implementing the program in the front line [28, 30]. In the training conducted in Changchun, participants showed enthusiasm towards the training by positive registering, learning, discussing, reflecting and sharing. In the present study, subjective outcome evaluation was used to examine the efficacy of this training program.

The present research findings demonstrate an overall success of the training program. Consistent with the previous training programs conducted in Hong Kong and other mainland cities, the training program received very positive feedbacks from the participants [25, 26, 28]. Overall speaking, the quantitative evaluation results showed that a very high percentage of the participants were satisfied with the program content, instructors and administrative arrangement. Besides, majority of the participants agreed that they gained a higher level of

competence in teaching PYD curriculums through this training and optimistic about the implementation of the project in the future. The present study also replicated previous evaluation findings that both junior and senior high school teachers held positive views towards the training program [15]. Thus, we concluded that the training program was well-received in the mainland China. As some studies suggest a positive correlation between subjective outcome and objective outcome evaluation findings [31-33], it is conjectured that the teachers might possibly perform well in their actual teaching. Of course, future studies should examine whether teachers' positive perceptions of the training predict successful objective outcomes of the project in mainland China.

The present study also identified factors that contributed to a successful training program. Participants' perceived program quality as the strongest predictor of their perceived program benefits and their overall satisfaction, which was in line with the findings of previous trainings in mainland China [34-36]. The participants in Changchun training demonstrated an overall satisfaction with the program quality. This finding suggests that in future training programs, training implementers may use Changchun training design as a reference, such as using more interactive training methods and activities, being sensitive to teachers' needs and expectation, and encouraging peer interaction and self-reflection. In addition to the perceived quality of program and instructor, participants' self-performance and administrative arrangements of the training were also found to be important predictors of perceived program benefits. Hence, it is important for the trainers to have a holistic view when designing the training, and to take all these program components, including program quality, instructor quality, self-performance and administrative arrangements, into account [37].

Although the present study provides strong evidence that the training in Changchun is beneficial to the program participants, some limitations should be noted. First, subjective outcome evaluation in the present study was limited to quantitative data only. Although the quantitative approach is cost-effective and it favors objectivity, representativeness and generalization, qualitative approach is an important alternative or complementary evaluation method which can help to develop an in-depth understanding of the program benefits [38]. Thus, qualitative evaluation of subjective outcomes (e.g., in-depth individual interview and focus group interview) should be included in future research to generate an integrated picture of effectiveness. Second, in addition to subjective evaluation, objective outcome evaluation is also recommended which can give a better understanding of training effectiveness in implementing the project in mainland China. Third, other factors that could affect participants' subjective evaluation of training, such as teachers' previous training attendance record and program implementation experiences, should be included in future studies. Despite the limitations above, the favorable evaluation findings suggest that the Changchun training program for the Project P.A.T.H.S. is well received in mainland China.

ACKNOWLEDGMENTS

The preparation for this paper and the Tin Ka Ping P.A.T.H.S. Project are financially supported by Tin Ka Ping Foundation. This chapter is a reprint with minor revisions of an earlier published paper in the *International Public Health Journal* 2018;10(1) issue with permission.

APPENDIX. CONTENT OF THE THIRD TRAINING PROGRAM IN THE 2015-2016 ACADEMIC YEAR IN CHANGCHUN, CHINA

Junior Group

Day 1 (6.5 hours)	
Themes and objectives	Activities conducted
Introduce the latest progress of the Tin Ka Ping P.A.T.H.S. Project in the full implementation phase (2015-2016); Offer opportunities for junior and senior school delegates, principals, and teachers to share their experiences; and Familiarize the participants with the teaching units related to the constructs of “Cognitive Competence” (CC).	Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team; Introduce the training schedules of the Project; Guide the participants how to use the updated teaching materials and other online resources on the website; Introduce the Co-Walker Scheme; Report the results of evaluation of the second training program in Shaoguan; School sharing from Changchun on the implementation progress of senior programs; Warm-up activities; Lecture on the constructs of “Cognitive Competence” (CC) and the contents of units; Sharing session from participatory schools.
Day 2 (6.5 hours)	
Themes and objectives	Activities conducted
Offer opportunities for schools from Changchun and other participatory schools to share their teaching experiences and demonstrate teaching techniques; and Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project.	Warm-up activities; Lesson demonstrations by experienced school teachers from participating schools; Group discussion and Q&A session.
Day 3 (6.5 hours)	
Themes and objectives	Activities conducted
Familiarize the teachers with the constructs and teaching units; Clarify participants’ questions on project implementation; and Familiarize the participants with the teaching units related to the constructs of “Moral Competence” (MC) and “Self-Determination” (SD) Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project.	Warm-up activities; Group discussions on “How to be a good P.A.T.H.S. teacher?”, “How to teach a good lesson of P.A.T.H.S.?”, and “How to implement P.A.T.H.S. much better?” Lecture on the constructs of “Moral Competence” (MC) and the contents of units; Sharing session from participatory schools.
Day 4 (6.5 hours)	
Themes and objectives	Activities conducted
Familiarize the teachers with the constructs and teaching units; Clarify participants’ questions on project implementation; Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project; and Familiarize the participants with the teaching units related to the constructs of “Self-Determination” (SD), “Spirituality” (SP), and “Clear and Positive Identity” (ID).	Warm-up activities; Lecture on the constructs of “Self-Determination” (SD) and the contents of the unit; Lecture on the constructs of “Spirituality” (SP) and the contents of the unit; Lecture on the constructs of “Clear and Positive Identity” (ID) and the contents of the unit; Sharing session from participatory schools; Interactive lecture on the teaching technique (Stress and fatigue for teachers); Introduce the evaluation results of 2015/16 academic year; Wrapping up and self-reflection; and Conclusion.

Appendix (Continued)

Senior Group	
Day 1 (6.5 hours)	
Themes and objectives	Activities conducted
Introduce the latest progress of the Tin Ka Ping P.A.T.H.S. Project during the full implementation phase (2015-2016); Familiarize the teachers with the constructs and teaching units.	Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team; Warm-up activities; Introduce the training schedules of the Project; Guide the participants how to use the updated teaching materials and other resources of Tin Ka Ping P.A.T.H.S. Project; Introduce the Co-Walker Scheme; Report the results of the second training program evaluation; Lecture on the constructs of “Social Competence (SC)” and the contents of the unit; Lecture on the constructs of “Emotional Competence (EC)” and the contents of the unit; Lecture on the constructs of “Behavioral Competence (BC)” and the contents of the unit; Sharing session from participatory schools; Group discussion and Q&A session
Day 2 (6.5 hours)	
Themes and objectives	Activities conducted
Offer opportunities for school delegates to share their implementation experiences and teaching plans; and Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project.	Lesson demonstration by school teachers from participating schools; Group discussion and Q&A session.
Day 3 (6.5 hours)	
Themes and objectives	Activities conducted
Familiarize the teachers with the constructs and teaching units. Clarify participants’ questions on project implementation; and Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project.	Warm-up activities; Lecture on the constructs of “Cognitive Competence” (CC) and the contents of the unit; Lecture on the constructs of “Self-Efficacy” (SE) and the contents of the unit; Lecture on the constructs of “Moral Competence” (MC) and the contents of the unit; Lecture on the constructs of “Behavioral Competence” (BC) and the contents of the unit; Group discussion on “How to be a good P.A.T.H.S. teacher?”, “How to teach a good lesson of P.A.T.H.S.?” and “How to implement P.A.T.H.S. much better?”
Day 4 (6.5 hours)	
Themes and objectives	Activities conducted
Familiarize the teachers with the constructs and teaching units; Clarify participants’ questions on project implementation; and Familiarize the participants with teaching method of the Tin Ka Ping P.A.T.H.S. Project.	Warm-up activities; Lecture on the constructs of “Behavioral Competence” (BC) and the contents of the unit; Lecture on the constructs of “Social Competence” (SC) and the content of the unit; Lecture on the constructs of “Resilience” (RE) and the contents of the unit; Sharing session from participatory schools; Interactive lecture on the teaching technique (Stress and fatigue for teachers); Introduce the evaluation results of 2015/16 academic year; Wrapping up and self-reflection; and Conclusion.

ABSTRACT

The Tin Ka Ping (TKP) P.A.T.H.S. Project is a pioneer positive youth development program implemented in China. In this study, subjective outcome evaluation data from two junior secondary schools in mainland China were used to reach a tentative understanding of students' opinions about program design, program instructors, and benefits of the program. Consistent with previous findings in Hong Kong, the great majority of the students showed positive feelings of the program content, instructors, and program effectiveness. As predicted, program content, instructors, and effectiveness were significantly inter-correlated. Perceived program content and quality of instruction were also identified to be significant predictors of program effectiveness perceived by student participants. The present findings suggest that TKP P.A.T.H.S. program was well received by the students in mainland China.

INTRODUCTION

In the past few decades, positive youth development (PYD) approach has been widely used to promote holistic development for youths and young adults in Western countries [1, 2]. Additionally, the approach is well adopted in the Chinese contexts [3, 4]. In Hong Kong, the P.A.T.H.S. Project was designed utilizing 15 constructs of positive adolescent development recognized in the scientific literature [5]. Systematic evaluation studies of the programs in the P.A.T.H.S. Project have shown that they have helped promote adolescent well-being and delayed the onset of risk behavior [6-8].

In terms of youth issues, it is noteworthy that adolescents in mainland China show many forms of risk behavior [9, 10]. With a highly competitive education system, young people on the mainland also face very high academic stress. It is important to ask how we can promote holistic development for Chinese students in mainland China. Obviously, with the successful implementation experience of the P.A.T.H.S. Project in Hong Kong, it is expected that the project could be further transplanted to mainland China, where has similar cultural context with Hong Kong. Financially the P.A.T.H. Project was fully supported by Tin Ka Ping (TKP) Foundation. The P.A.T.H.S. Project was preliminary transplanted as a pilot scheme to four schools in Shanghai, Suzhou, Changzhou and Yangzhou in eastern China since 2011. During 2011-2014, teaching materials in simplified Chinese were developed by the Hong Kong Research Team, and teacher training and program evaluation were also implemented in mainland China. Because of the extensive support from TKP schools located throughout the country, the second phase (preparatory phase) of the project was launched in fall 2014, with the objective of providing systematic training and “trial” experience for the school teachers who are the potential instructors of the project [11]. In 2014-15 school year, four training programs had been offered in three different cities in eastern or western China, including Shanghai, Suzhou and Chongqing [12-15]. Besides attending the training programs, some schools also tried out the program.

To facilitate systematic evaluation of the TKP P.A.T.H.S. Project, the Research Team briefed the teachers in the training programs regarding the three major project evaluation strategies: (a) objective outcome evaluation using validated scales; (b) subjective outcome evaluation on the base of the replies in Form A (for the program participants) and Form B (for the program implementers), and (c) qualitative evaluation such as collection of students' diaries. With particular reference to the views of the program participants, the instrument used in evaluation (i.e., Form A) has three primary dimensions (program content, program instructors, and program effectiveness), which had excellent psychometric properties [16]. The adoption of Form A as an evaluation tool has three advantages. First, we can aggregate data from multiple years that can show a general profile of the responses of participants. Second, the tool has been validated with excellent psychometric properties. Finally, subjective outcome evaluation is a relatively economical way to conduct program evaluation [17, 18].

The objective of the present study was to investigate the views of the student participants' on the TKP P.A.T.H.S. program implemented in mainland China. Three sets of research questions were addressed in the study:

- Question 1: What are student participants' perceptions of the program content, program instructors (teachers), and program effectiveness? Based on previous studies conducted in Hong Kong, it was predicted that the participants would be satisfied with the program content, program instructors and program effectiveness (Hypothesis 1).
- Question 2: What are the inter-relationships amongst program content, quality of instruction, and program effectiveness perceived by the participants? Based on the literature, it was expected that there would be a correlation between perceived program content and program instructors (Hypothesis 2a), perceived program content and program effectiveness (Hypothesis 2b), and perceived program instructors and program effectiveness (Hypothesis 2c).
- Question 3: What are the predictors of perceived program effectiveness? Based on previous findings, we predicted that perceived program content and program instructors would predict program effectiveness (Hypothesis 3a and 3b).

OUR STUDY

In the 2014–15 school year, data was collected using the questionnaire Form A from two schools (N = 521). Both schools followed the standardized instructions regarding student data collection and data entry that were given in Form A and provided by the Research Team. Passive informed consent was obtained from the student participating in the program at the beginning of the survey. The students could withdraw from the study if they did not want to participate. All students filled out the survey in a self-administered manner.

Instruments

Form A assesses the subjective views of the program participants. It was widely used in different schools in the Hong Kong P.A.T.H.S. Project. Program participants were invited to use Form A to share their perceptions of program content, program instructors (teachers, social workers, other workers), and program effectiveness after participating in TKP P.A.T.H.S. Project. From the findings in previous evaluation research, it has been found that Form A possesses excellent psychometric properties [16]. Form A includes five parts:

- *Part 1 (participants' evaluations of the program content)*. There are 10 items, which include students' perceptions of the curriculum objectives, course design, interaction with the instructors, and student participation in learning. Details of the items are shown in Table 1.
- *Part 2 (participants' evaluation of the program instructors)*. There are 10 items including students' perception of the teaching, class preparation, the teachers' professional attitude, and the teachers' caring and supportive attitude. Details of the items are shown in Table 2.
- *Part 3 (participants' evaluation of program effectiveness)*. There are 16 items assessing students' perception of the program benefits to their PYD, such as

promotion of bonding, emotional competence, social skills and competence, or moral competence. Details of the items are shown in Table 3.

- *Part 4 (participants' overall satisfaction with the program).* There are three items measuring satisfaction. They inquire whether the students will recommend their friends to join the program, whether the students would like to participate in similar programs again, and the students' global satisfaction with the TKP P.A.T.H.S. program.
- *Part 5 (four open-ended questions).* Students are invited to share their views and feelings on things they learned and appreciated, to give suggestions to the teachers, and recommendations for the program.

Data Analyses

SPSS 23 (IBM SPSS Statistics, IBM Corp, Somers, NY) was used for all the data analyses. Four subscale variables were created: (a) "program content (VC)" was the mean score of the 10 items in Part 1; (b) "program instructors (VI)" was the mean score of the 10 items in Part 2; (c) "program effectiveness (EF)" was the mean score of the 16 items in Part 3; (d) "total effectiveness" was calculated as the overall mean score of all the 36 items in Part 1, 2, and 3. Data analyses in this study only covered the quantitative data in Part 1 to Part 4.

Descriptive analyses were conducted to calculate the mean and standard deviations of each subscale. Reliability analyses were performed to measure the internal consistency of the above subscales and the overall scale. Pearson correlation coefficients were also calculated to examine interrelationships amongst the variables. Lastly, multiple regression analyses were performed to examine whether perceived program content and instructors predict program effectiveness. All the above analyses were conducted for the two schools (School 1 and School 2) separately and aggregately.

FINDINGS

Form A showed good psychometric properties. As the findings shown in Table 4, the scale had good internal consistency in School 1, School 2, and the overall sample. In the overall sample ($N = 521$), the reliability estimates were good: the Cronbach's alpha value for the total effectiveness scale was .96, and the Cronbach's alpha values for the subscales of program content, program instructors, and program effectiveness were .88, .93 and .94 respectively; the mean of inter-item correlation for the scale and subscales above, respectively was .38, .42, .56, and .51.

Descriptive analyses showed that the majority of the student participants evaluated the program positively regarding its content, instructors (teachers, social workers, other workers), as well as its effectiveness. As shown in Table 1, 89.8% of the participants had a positive view on the good design of the curriculum (item 2), 91.9% of the participants agreed that the curriculum objectives were very clear (item 1), and 91.0% of the participants had overall satisfaction of the curriculum (item 10). As shown in Table 2, amongst the top items rating program instructors, 96.0% of the participants agreed that the teachers had encouraged them

to participate in different course activities (item 6), 95.0% of the participants agreed that they received timely help from the teachers (item 8) and 95.4% of the participants had a positive perception of the active involvement of the teachers (item 5).

Table 1. Descriptive statistics of the participants' evaluations of the program content

	Respondents with positive responses (Options 4-6)					
	School 1		School 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
1) The objectives of the curriculum are very clear.	117	95.9	362	90.7	479	91.9
2) The design of the curriculum is very good.	119	97.5	349	87.5	468	89.8
3) The activities were carefully planned.	116	95.1	337	84.5	453	86.9
4) The classroom atmosphere was very pleasant.	110	90.2	325	81.5	435	83.5
5) There was much peer interaction amongst the students.	118	96.7	332	83.2	450	86.4
6) I participated actively during lessons (including discussions, sharing, games, etc.).	117	95.9	334	83.4	451	86.6
7) I was encouraged to do my best.	116	95.9	333	83.5	449	86.3
8) The learning experience I encountered enhanced my interest towards the lessons.	114	94.2	336	84.2	450	86.5
9) Overall speaking, I have a very positive experience of the program.	115	95.0	331	83.0	446	85.8
10) On the whole, I like this curriculum very much.	119	98.3	354	88.7	473	91.0

Note: All items are measured using a 6-point Likert scale where 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

Table 2. Descriptive statistics of the participants' evaluations of the program instructors

	Respondents with positive responses (Options 4-6)					
	School 1		School 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
1) The instructor(s) had a good mastery of the curriculum.	120	98.4	354	88.7	474	91.0
2) The instructor(s) was well prepared for the lessons.	121	99.2	362	90.7	483	92.7
3) The instructor(s)' teaching skills were good.	120	98.4	360	90.2	480	92.1
4) The instructor(s) showed good professional attitudes.	118	96.7	368	92.2	486	93.3
5) The instructor(s) was very involved.	119	98.3	377	94.5	496	95.4
6) The instructor(s) encouraged students to participate in the activities.	121	99.2	379	95.0	500	96.0
7) The instructor(s) cared for the students.	121	99.2	365	91.5	486	93.3
8) The instructor(s) was ready to offer help to students when needed.	121	99.2	374	93.4	495	95.0
9) The instructor(s) had much interaction with the students.	117	95.9	353	88.5	470	90.2
10) Overall speaking, I have a very positive experience of the instructors.	121	99.2	372	93.2	493	94.6

Note: All items are measured using a 6-point Likert scale where 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

Table 3. Descriptive statistics of the participants' evaluations of the program effectiveness

	Respondents with positive responses (Options 3-5)					
	School 1		School 2		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
1) It has strengthened my bonding with teachers, classmates, and my family.	112	91.8	284	71.2	396	76.0
2) It has strengthened my resilience in adverse conditions.	111	91.0	316	79.2	427	82.0
3) It has enhanced my social competence.	114	93.4	328	82.2	442	84.8
4) It has improved my ability in handling and expressing my emotions.	115	94.3	324	81.2	439	84.3
5) It has enhanced my cognitive competence.	115	94.3	325	81.5	440	84.5
6) My ability to resist harmful influences has been improved.	116	95.1	344	86.2	460	88.3
7) It has strengthened my ability to distinguish between the good and the bad.	118	96.7	346	86.7	464	89.1
8) It has increased my competence in making sensible and wise choices.	115	94.3	333	83.5	448	86.0
9) It has helped me to reflect my life.	113	93.4	310	77.7	423	81.3
10) It has reinforced my self-confidence.	113	92.6	319	79.9	432	82.9
11) It has increased my self-awareness.	117	96.7	344	86.2	461	88.7
12) It has helped me to face the future with a positive attitude.	119	97.5	334	83.7	453	86.9
13) It has helped me to cultivate compassion and care for others.	114	93.4	321	80.5	435	83.5
14) It has encouraged me to care about the community.	101	82.8	256	64.2	357	68.5
15) It has promoted my sense of responsibility in serving the society.	110	90.9	320	80.2	430	82.7
16) It has enriched my overall development.	119	97.5	355	89.2	474	91.2

Note: All items are measured using a 5-point Likert scale where 1 = unhelpful, 2 = not really helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3-5) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

Table 4. Mean, standard deviations, Cronbach's alphas, and the mean of inter-item correlations

	School 1		School 2		Overall	
	M (SD)	α (Mean [#])	M (SD)	α (Mean [#])	M (SD)	α (Mean [#])
Program content (10 items)	5.46 (.66)	.90 (.48)	4.60 (.71)	.83 (.33)	4.80 (.79)	.88 (.42)
Program instructors (10 items)	5.68 (.53)	.93 (.59)	4.90 (.77)	.91 (.50)	5.08 (.79)	.93 (.56)
Program effectiveness (16 items)	4.34 (.76)	.96 (.63)	3.51 (.77)	.92 (.42)	3.70 (.84)	.94 (.51)
Total effectiveness (36 items)	5.02 (.59)	.97 (.45)	4.20 (.62)	.94 (.30)	4.39 (.70)	.96 (.38)

Note: School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

[#] Mean inter-item correlations.

Table 5. Other aspects of subjective outcome evaluation based on the participants' perception

If your friends have needs and conditions similar to yours, will you suggest him/her to join this course?

Respondents with positive responses (Options 3-4)					
School 1		School 2		Overall	
<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
121	100.0	365	91.5	486	93.5

Note: The item is measured using a 4-point Likert scale where 1 = definitely will not suggest, 2 = will not suggest, 3 = will suggest, 4 = definitely will suggest. Only respondents with positive responses (Options 3-4) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

Would you participate in similar courses again in the future?

Respondents with positive responses (Options 3-4)					
School 1		School 2		Overall	
<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
119	98.3	371	93.0	490	94.2

Note: The item is measured using a 4-point Likert scale where 1 = definitely would not participate, 2 = would not participate, 3 = would participate, 4 = definitely would participate. Only respondents with positive responses (Options 3-4) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

On the whole, are you satisfied with this course?

Respondents with positive responses (Options 4-6)					
School 1		School 2		Overall	
<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
121	100.0	370	92.7	491	94.4

Note: All items are measured using a 6-point Likert scale where 1 = very dissatisfied, 2 = moderately dissatisfied, 3 = slightly dissatisfied, 4 = satisfied, 5 = moderately satisfied, 6 = very satisfied. Only respondents with positive responses (Options 4-6) are shown in the table. School 1: Shijiazhuang TKP school, School 2: Shanwei TKP school.

Table 6. Pearson correlations among program content, instructors, and effectiveness

School 1: Variable	1	2	3
1) Program content (10 items)	-		
2) Program instructors (10 items)	.71**	-	
3) Program effectiveness (16 items)	.59**	.58**	-

** $p < .01$.

School 2: Variable	1	2	3
1) Program content (10 items)	-		
2) Program instructors (10 items)	.60**	-	
3) Program effectiveness (16 items)	.51**	.45**	-

** $p < .01$.

Overall : Variable	1	2	3
1) Program content (10 items)	-		
2) Program instructors (10 items)	.69**	-	
3) Program effectiveness (16 items)	.61**	.56**	-

** $p < .01$.

Regarding students' perception on their personal growth after the program, some items received high ratings. As Table 3 shows, 89.1% of the participants agreed that the program had improved their ability to distinguish between the good and the bad (item 7), 88.7% of the participants had a positive perception of their increased self-awareness (item 11), and 91.2% of the participants agreed that the program had enriched their overall development (item 16). In Table 5 we can see that 93.5% of the students would suggest their friends to join the program, 94.2% would participate in a similar program in the future, and 94.4% were satisfied with the program they participated. These findings provided support to hypothesis 1.

Table 7. Multiple regression analyses predicting program effectiveness by program content and instructors

	Predictors		Model	
	Program content	Program instructors		
	β^a	β^a	R	R ²
School 1	.36**	.33**	.64	.40
School 2	.37***	.23***	.54	.28
Overall	.44***	.26***	.64	.41

a Standardized coefficients.

** $p < .01$, *** $p < .001$.

Pearson correlation analyses (see Table 6) showed that program content (VC), instructors (VI) and effectiveness (EF) were all positively and significantly correlated: VC and VI ($r = .69, p < .01$); VC and EF ($r = .61, p < .01$); VI and EF ($r = .56, p < .01$). This means that hypotheses 2a, 2b, 2c were all supported. Multiple regression analyses (see Table 7) demonstrated that how the students' perceived the program content (VC) and program instructors (VI) significantly predicted their perceived program effectiveness (EF). In the total sample, both VC ($\beta = .44, p < .001$) and VI ($\beta = .26, p < .001$) significantly predicted EF, and accounted for 41% of the total variance of EF. These findings provided support for hypothesis 3a and hypothesis 3b.

DISCUSSION

Similar to previous evaluations in Hong Kong [16, 19-21], Form A was shown to be a reliable evaluation tool of subjective outcome to assess the views of the student participants on the P.A.T.H.S. program implemented in the two middle schools in mainland China. Most important of all, the students had a very positive view on the program content, instructors, and benefits brought to their personal development. The evaluation findings clearly give preliminary support that TKP P.A.T.H.S. Project is an effective and promising program in the two schools which participated in the preparatory phase in 2014-15 school year.

With regard to the inter-relationships amongst the three aspects of subjective outcome evaluation, results of Pearson correlation analyses showed that program content, program instructors (teachers, social workers, other workers), and program effectiveness are the "holy trinity" of the subjective outcome evaluation [22]. Besides, results showed that student participants' perceived program content and instructor quality significantly predicted their perceived program effectiveness, which covered different aspects of PYD. From the student

participants' perspective, the P.A.T.H.S. curriculum was perceived as very beneficial to the development of adolescent.

The present study is a pioneer evaluation study of the project in mainland China. However, it has several limitations. First, common method variance may account for the significant inter-relationships amongst the different components of subjective outcome evaluation. Second, as only two schools were involved in the evaluation, the findings should be treated as tentative in nature. Third, in addition to subjective outcome evaluation, other forms of evaluation (such as qualitative methods) should be included in the evaluation model. Finally, besides students, other major stakeholders should be included to achieve a more comprehensive view of the impact of the program.

Chapter 326

EVALUATION FINDINGS OF TIN KA PING P.A.T.H.S. PROJECT IMPLEMENTED IN JUNIOR SECONDARY SCHOOLS: IMPLEMENTERS' VIEWS

***Daniel T. L. Shek*, PhD, FHKPS, BBS, SBS, JP,
Xiaoqin Zhu, PhD and Janet T. Y. Leung, PhD***

Department of Applied Social Sciences, The Hong Kong Polytechnic University,
Hung Hom, Hong Kong, PR China

ABSTRACT

After the Project P.A.T.H.S. was successfully implemented in the pilot stage in four cities in East China, the project was implemented on a full-scale basis since 2015-2016 academic year. The present paper outlines the evaluation findings of the first year during the full implementation based on the views of the implementers using the subjective outcome evaluation approach. A total of 144 implementers from 13 secondary schools joined the current research. On the whole, results showed that the implementers were highly satisfied with the implementation regarding program content, their own performance, and program benefits. As expected, perceptions of program content and implementers' own performance were positively associated with perceived program benefits. Together with previous evaluation findings in Hong Kong and China mainland, the current study suggests that the Project P.A.T.H.S. has been well received by participants and implementers, and it promotes positive development in adolescents in different Chinese communities.

INTRODUCTION

Positive youth development (PYD) programs are intended to promote all-round development among teenagers by providing them opportunities to recognize, utilize and

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

enhance their strengths, which would establish a solid foundation for healthy adjustment which would eventually prevent youth problems, such as substance abuse, juvenile delinquency, and violent crimes [1]. The beneficial influence of PYD programs has been widely recognized globally. For instance, sport camps in the United Kingdom (UK) have been shown to promote competence, confidence, and care amongst students [2]. In South Africa, a narrative-based program was found to promote youth development and it successfully reduced alcohol use and HIV infection among the youngster [3]. In a comprehensive review of efficacious youth programs around the world, researchers concluded that implementing preventive and PYD programs effectively is a promising way to reduce adolescent problem behaviors [4].

Although PYD programs are popular among Western countries, systematic and large-scale PYD programs are rarely developed and implemented in Chinese contexts [5]. To fill this information gap, a curriculum-based PYD program entitled “Positive Adolescent Training through Holistic Social Programmes” (Project P.A.T.H.S.) was developed and carried out in Hong Kong since 2005-2006 academic year with the financial support of The Hong Kong Jockey Club Charities Trust. This is the first large-scale and holistic PYD program in different Chinese communities. During the past decade, this project has achieved a great success in competence building and problem prevention among Hong Kong adolescents. Specifically, empirical findings showed that the project successfully enhanced multiple developmental assets and well-being (e.g., self-confidence, spirituality, prosocial involvement, and social competence) in students while simultaneously reduced adolescents’ engagement in maladaptive behaviors, such as drug abuse, delinquency, and self-harm activities [6-8]. Consistently, the program was positively evaluated and regarded as effective by both adolescent participants and program implementers [9-11]

There is also an urgent need to design and launch evidence-based PYD programs in mainland China because there are growing trends of youth problems in China. For example, with rapid economic growth in the past decades in mainland China, materialism became prevalent among Chinese adolescents. According to a research conducted by Ipsos [12], China is now the most materialistic country among 20 countries including the United States, UK, Japan, Korea, and so on. Under this atmosphere, the younger generation in China is becoming more materialistic when compared to the older generation and their counterparts in other countries [13]. It is noteworthy that materialism was adversely associated with healthy adolescent development, such as self-esteem, mental health, and life satisfaction [14]. Similarly, an orientation of materialism also exerts negative impacts on students’ intrinsic learning motivation, school performance, and developmental outcomes [15]. All these findings take place alongside with the growing trends of external and internal problems among the Chinese youths [16].

To promote health development in Chinese adolescents in mainland China, the Project P.A.T.H.S. was adapted and implemented in mainland China in 2011, with financial support from Tin Ka Ping Foundation. Although the Project P.A.T.H.S. has benefited thousands of secondary students in Hong Kong, its effectiveness in mainland China remains uncertain due to several reasons. First, although the junior secondary school programs adopted in mainland China were based on those implemented in Hong Kong, their applicability is unclear because there are cultural or sub-cultural differences involved.

Second, the pedagogy of Project P.A.T.H.S. was based on experiential learning, which requires teachers to let students learn from their firsthand experience rather than only

passively receiving knowledge from teachers [17]. In particular, it emphasizes reflection since it allows students to introspect challenges and integrate new information to their existing schema [17]. Obviously, such a student-centered pedagogy is quite different from the traditional teacher-centered one adopted in China. This stimulating pedagogy requires both teachers and students to make adaptations to their changing roles in the classroom. In this sense, both teachers and students may have difficulties in adjusting to the new teaching and learning styles, which might also potentially affect the effectiveness of the project.

Third, implementing and participating in such a PYD program might require extra working and schooling hours from teachers and students. Given that academic achievement is morbidly emphasized by schools, parents, and the society in China [18], school teachers and students may still have a mindset that the Project P.A.T.H.S. is competing for resource with other academic courses, which might possibly hinder students' academic achievement. Despite the strong evidence that effective PYD programs can actually enhance adolescents' school performance and academic achievement [19], schools might still have hesitation to devote sufficient effort in implementing the project.

In view of the above issues, a 3-year pilot implementation (i.e., from 2011-2012 to 2013-2014 academic year) was carried out in four secondary schools located in East China and different evaluation strategies were utilized to investigate the implementation effectiveness. Results revealed highly positive findings regarding the program effectiveness in promoting adolescent holistic development [20, 21]. These encouraging findings motivated the Foundation to support the project for three more years (2015-2016 to 2017-2018 school years) after one-year of preparation (i.e., 2014-2015 school year).

Although the pilot implementation showed the benefits of the Tin Ka Ping Project P.A.T.H.S. in China mainland, continuous program evaluation should be carried out, not only for the purpose of providing evidence-based support but also informing directions to improve future implementation. To this end, the present study attempted to evaluate program effectiveness in the first year of full implementation (i.e., 2015-2016 academic year). A subjective outcome evaluation method was used, in which data on the views from the program implementers toward three main aspects (program content, implementer's own performance, and program effectiveness) were collected. Program implementers' views should be considered and understood because they directly deliver the program. Moreover, their direct interactions with students allow them to understand the real need and actual change of students. Based on the previous positive evaluation findings [11, 22, 23], we proposed the following hypotheses:

- A majority of the program implementers would show positive perceptions on program content (Hypothesis 1a), their own performance (Hypothesis 1b), and program effectiveness (Hypothesis 1c). In subjective outcome studies, a program is commonly regarded as positive if more than 80% of the respondents respond in the positive direction. We used the same cutoff point in this study.
- Program implementers' satisfaction of program content (Hypothesis 2a) and self-perceived performance (Hypothesis 2b) would have positive relationships with the perceived program effectiveness.

- Program implementers’ evaluation of program effectiveness would be positively predicted by perceived program content (Hypothesis 3a) and own performance (Hypothesis 3b).

OUR STUDY

Program implementers (e.g., teachers) from 13 participating schools were invited to complete a subjective outcome evaluation form for implementers (i.e., Form B) after the program was implemented in 2015-2016 academic year. A total of 144 implementers completed and returned the Form B. Among all the implementers, 80 implemented the program for Secondary 1, 45 for Secondary 1 and Secondary 2, and 19 for Secondary 1, Secondary 2, and Secondary 3. The number of implementers in each school ranged from 5 to 30, with an average of 11 (*SD* = 6.79). An evaluation manual with detail instructions was given to implementers to guide them to complete the Form B prior to program evaluation. The procedures for collecting data and the related instructions were also covered in the training workshops.

Instruments

The Form B used in the present study has been widely used in prior evaluation studies and proved to be valid and reliable [11, 24]. In Form B, six parts were developed to measure implementers’ subjective perceptions of several aspects of the program.

First, two subscales were included in Part 1. Each subscale adopted 10 items to measure perceptions of the implementers toward the program content (e.g., impression of the program, classroom atmosphere, and students’ participation) and self-performance (e.g., implementers’ understanding of the program, involvement, and teaching skills). For each statement, the implementers gave their response on a 6-point Likert scale (1= strongly disagree, 6 = strongly agree). The higher they rated, the more they agreed with the statement. The two subscales in the first part showed good reliability in the present study (see Table 1).

Table 1. Mean, standard deviation, Cronbach’s alphas, and mean of inter-item correlations among variables

	M	SD	Cronbach’s α	Mean [#]
Program content (10 items)	5.28	.49	.89	.44
Program implementers (10 items)	5.12	.56	.92	.52
Program effectiveness (16 items)	4.23	.59	.96	.59

Note. [#] Mean inter-item correlations

Second, 16 items were employed in Part 2 to evaluate the implementers’ perceived program effectiveness (e.g., improvement in students’ resilience, emotional competence, and social competence). This subscale utilized a 5-point Likert scale (1 = not helpful at all, 5 = very helpful). Similarly, a higher rating in this subscale indicates a higher level of perceived program effectiveness. This subscale also had good reliability as shown in Table 1.

For Part 3 to Part 5, each part only contained one question. The third part asked the implementers to indicate their willingness to recommend the program to students having similar needs on a 4-point Likert scale (1 = definitely will not, 4 = definitely will). Using the same 4-point scale (1 = definitely will not, 4 = definitely will), the fourth part invited the implementers to express their willingness in teaching similar courses in the future. Lastly, the question in the fifth part was designed to assess the implementers' perception of the extent to which the program helped their professional development. Implementers gave their responses on a 5-point Likert scale (1 = not helpful at all, 5 = very helpful).

The sixth part contained three open questions about the most appreciated elements of the program, the areas need improvement, and suggestions for future development. In the present paper, the focus is put on the quantitative data derived from the first five parts.

Data Analyses

A reliability test was done to measure the internal consistency of each subscale. Descriptive analyses were then performed to calculate the percentage of favorable responses of each part. We also examined correlations among respondents' views toward program quality, their own performance, and program effectiveness. Besides, a multiple regression analysis was performed to examine the predictive effect of perceived program qualities and self-perceived performance on the level of perceived program effectiveness.

FINDINGS

Using 80% as a cutoff, positive responses toward the program content were found among all items as shown in Table 2. For example, all implementers agreed that the objectives of the program were very clear and the program activities were carefully designed. Moreover, almost all implementers (99.3%) had a very positive overall evaluation on the program and agreed that their students like this program very much.

Table 2. Summary of the program implementers' perceptions toward the program content

	Positive responses (Options 4-6)	
	N	%
1. The objectives of the curriculum are very clear.	144	100.0
2. The design of the curriculum is very good	143	99.3
3. The activities were carefully planned	144	100.0
4. The classroom atmosphere was very pleasant.	142	98.6
5. There was much peer interaction amongst the students	137	95.1
6. Students participated actively during lessons (including discussions, sharing, games, etc.)	141	97.9
7. The program has a strong and sound theoretical support.	141	97.9
8. The teaching experience I encountered enhanced my interest towards the lessons	142	98.6
9. Overall speaking, I have very positive evaluation of the program	143	99.3
10. On the whole, students like this curriculum very much	143	99.3

Note. All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Similar positive results were found in self-perceived performance (see Table 3). All implementers stated that they were ready to offer help to student when needed. Most of them (99.3%) had a very positive overall evaluation on themselves. Highly positive responses were also found on other items (e.g., professional attitude, involved, and cared for students).

Table 3. Summary of the program implementers' perceptions toward their own performance

	Positive responses (Options 4-6)	
	N	%
1. I have a good mastery of the curriculum.	136	94.4
2. I prepared well for the lessons	138	95.8
3. My teaching skills were good	137	95.1
4. I have professional attitude	142	98.6
5. I was very involved	141	97.9
6. I gained a lot during the course of instruction	142	98.6
7. I cared for the students	142	98.6
8. I was ready to offer help to students when needed	144	100.0
9. I had much interaction with the students	141	97.9
10. Over speaking, I have very positive evaluation of myself as an instructor	143	99.3

Note. All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Table 4. Summary of the program implementers' perceptions toward the program effectiveness

	Positive responses (Options 3-5)	
	N	%
1. It has strengthened students' bonding with teachers, classmates and their families	143	99.3
2. It has strengthened students' resilience in adverse conditions	141	97.9
3. It has enhanced students' social competence	140	97.2
4. It has improved students' ability in handling and expressing emotions	142	98.6
5. It has enhanced students' cognitive competence	141	97.9
6. Students' ability to resist harmful influences has been improved	141	97.9
7. It has strengthened students' ability to distinguish between the good and the bad	142	98.6
8. It has increased students' competence in making sensible and wise choices	141	97.9
9. It has helped students to have life reflections	141	97.9
10. It has reinforced students' self-confidence	142	98.6
11. It has increased students' self-awareness	142	98.6
12. It has helped students to face the future with a positive attitude	143	99.3
13. It has helped students to cultivate compassion and care about others	142	98.6
14. It has encouraged students to care about the community	139	96.5
15. It has promoted students' sense of responsibility in serving the society	142	98.6
16. It has enriched the overall development of the students	138	95.8

Note. All items are on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3-5) are shown in the table.

Table 4 presents the respondents' subjective views on perceived program effectiveness. Overall speaking, respondents gave highly positive responses on all items. More specifically, almost all participants (99.3%) agreed that the program helped their students build a stronger bonding with teachers, classmates and their families, and they perceived their students had a positive attitude to face the future after joining the program. Moreover, nearly 99% of the

implementers indicated that the program strengthened students' ability in expressing emotions, helped students to distinguish between good and bad, and cultivated compassion and care about others.

Table 5. Summary of the program implementers' positive perceptions on other aspects

Items	Positive responses (Options 3-4)	
	N	%
Willingness to suggest other students to participate in the program ^a	143	99.3
Willingness to teach similar programs in future ^a	139	96.5
The extent to which the program helped implementers' professional growth ^b	139	96.5

Note. ^a A 4-point Likert scale was used, with 1 = definitely will not, 2 = will not, 3 = will, 4 = definitely will. Only respondents with positive responses (Options 3–4) are shown in the table.

^b A 5-point Likert scale was used, with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3–5) are shown in the table.

Table 6 shows the results of Pearson correlation analyses. Both perception of program quality ($r = .58$, $p < .001$) and view toward own performance ($r = .66$, $p < .001$) showed a significant and positive linkage with implementers' perception of program effectiveness. These results provided support for hypotheses 2a and 2b.

Table 6. Correlations among perceptions on program content, implementers, and program effectiveness

Variable	Program effectiveness		
	1	2	3
1. Program content (10 items)	--		
2. Program implementers (10 items)	.74***		
3. Program effectiveness (16 items)	.58***	.66***	--

*** $p < .001$.

To further investigate the relationship between perceived program content, self-perceived performance and perceived program effectiveness, a multiple regression analysis was done and the results are depicted in table 7. Both implementers' self-perceived performance ($\beta = .50$, $p < .001$) and perceived program content ($\beta = .20$, $p < .05$) significantly predicted program effectiveness. The two predictors accounted for 45% of the variance of program effectiveness. In short, both hypotheses 3a and 3b were supported.

Table 7. Multiple regression analysis predicting program effectiveness

Program content	Predictors		Model
	Program implementers		
β^a	β^a	R	R^2
.20*	.50***	.67	.45

Note. ^a Standardized coefficients. *** $p < .001$. * $p < .05$.

DISCUSSION

The present research investigated evaluation findings based on implementers' views toward the Tin Ka Ping P.A.T.H.S. Project implemented in mainland China in 2015-2016 academic year. The current study employed a valid and reliable subjective outcome evaluation measurement (i.e., Form B) to assess the implementers' views toward the program implementation. The Form B mainly included three multi-item subscales that assessed implementers' perceptions of program content, their own performance and program effectiveness, respectively. The information of implementers' willingness to recommend the program to other students, willingness to implement similar programs in future, and the extent the experience promoted teachers' professional growth was also gathered in the present study. The present findings not only demonstrated that the program was effective. It also informed us about the possible factors that contributed to the implementation effectiveness.

Overall speaking, the implementers held positive perceptions of the program implemented in 2015-2016 school year. Notably, over 95% of the respondents gave positive ratings on all aspects of the program content; all of them regarded the curriculum objectives as clear and activities as meticulously designed; over 99% of them perceived that the curriculum was well designed and agreed that students loved the program a lot. In addition, the implementers held favorable views toward their own performance. Nearly or over 95% of them rated themselves as having good performance in all aspects. For instance, over 98% of the respondents perceived that they had professional attitudes, cared for the students, and were willing to offer help to the students.

Regarding perceived program effectiveness, results showed that the implementation of program was effective in cultivating students' myriad positive attributes, such as positive bonding with significant adults and peers, resilience, self-awareness, beliefs in the future, emotional and moral competence, and so on. Implementers' responses to the three questions illustrated in Table 5 reinforced the positive evaluation. Almost all respondents were willing to suggest other students to join the program, and approximately 97% of the implementers wished to teach similar course in future and felt that teaching the program had benefited themselves a lot regarding professional development. All these results coincide with the positive evaluation findings for the P.A.T.H.S. Project implemented in Hong Kong [11, 24], suggesting that the transplanting and adaptation of the project from Hong Kong to mainland China is successful.

Theoretically speaking, the well-designed program content and quality delivery of the content by implementers as well as some supportive external conditions (e.g., policy support) collaboratively ensure the great benefits enjoyed by program participants [25]. In line with this argument, perceptions of program content and program implementers' performance were both significantly correlated with and functioned as two significant predictors of perceived program effectiveness. The existing literature suggests that several factors may contribute to the quality of program content and implementers' good performance in delivering program content.

First of all, the curriculum of the project was developed based on PYD theory that maintains adolescents as "assets to be developed" instead of "problems to be solved" [26]. Based on this positive view of adolescents, course content was carefully selected to fulfill adolescents' developmental needs through promoting a wide range of psychosocial

competencies, including self-efficacy, emotional competence, spirituality, and resilience [27]. In addition to the strong theoretical basis, the curriculum also included a reflective and experiential learning pedagogy, which contends that students can learn by “experiencing, reflecting, thinking, and acting” [17]. In line with the active learning philosophy, the center of teaching shifted from teachers to students; the method of teaching ranged from merely lecturing to a combination of diverse ones, including group work, role play, debate, and reflection. It is noteworthy that an encouraging learning environment as well as a collaborative atmosphere created by such an inspirational and innovative pedagogy are very helpful in promoting students’ positive learning attitude, student engagement, and learning achievement [28, 29]. These two unique features of the program content lay a solid foundation for the success of the program implementation in mainland China.

Besides the solid groundwork linked to program content, the qualified implementer constitutes another indispensable prerequisite of effective program delivery. It was evident that the characteristics of teacher, such as teaching experience and support for students, could significantly affect student learning [30, 31]. Theories and empirical findings in the field of program evaluation also revealed that the quality of program implementers was a significant predictor of program effectiveness [5, 32]. In view of the critical role of program implementers in program implementation, a series of training program was rigorously designed based on a theoretical framework proposed by Shek and Wai [33] and offered to implementers in the preparation year and during the full implementation phase. As expected, these training programs helped implementers better understand the PYD theory and the curriculum design, cultivate the positive and enthusiastic attitude toward program implementation, and master the required teaching skills [34, 35]. Certainly, the comprehensive training enables the implementers to deliver the program effectively, which subsequently guarantees the benefits of the program.

While implementers gained confidence and experience in using experiential teaching method through training programs, positive findings of the present study also demonstrated that adolescents in mainland China can well adapt to the active learning style. In fact, instead of resisting the active pedagogy, students actually favored the student-centered approach and were able to actively participate in in-class activities involving interactions, critical thinking, self-reflections, sharing, and expression of personal views. This encouraging conclusion suggests that implementing PYD programs with active and experiential teaching and learning methods is a very promising way to promote holistic development in Chinese adolescents.

Despite the very positive findings, the present study has several limitations. First, our study only considered the implementers’ views. Besides, the sample size ($N = 144$) was not very large. To provide a full picture of program effectiveness and validate the present findings, future studies should involve other informants such as students and increase the sample size. Second, while acknowledging the advantages of subjective outcome evaluation approach, we also admit its inherent disadvantages. For example, reliability of subjective measures is affected by several factors that are hard, if not impossible, to control, such as item order and social desirability. Therefore, future studies could also include objective measures to offset these shortcomings. Third, although the present quantitative findings are very positive, it will certainly be illuminating to include qualitative methods such as focus group interview in future studies, as qualitative evaluation gives insight into the comprehensive picture of program effectiveness as well as mechanisms that underline the positive quantitative findings.

ABSTRACT

The Tin Ka Ping P.A.T.H.S. Project is an innovative positive youth development (PYD) program in mainland China with an aim to promote holistic development of Chinese secondary school students. Based on the subjective outcome evaluation approach, this study explored the effectiveness of the Tin Ka Ping P.A.T.H.S. Project in senior secondary schools in the 2015-2016 academic year from the perspective of students. A total of 1,762 senior secondary students from six participating schools completed the evaluation form. Findings suggested that a high proportion of the participants expressed positive attitudes towards the program, instructors' performance, and benefits of the program. Compared with Grade 11, Grade 10 students reported higher levels of satisfaction in all three aspects. In line with previous studies, the three dimensions had significant inter-relationships, and both program quality and instructor performance were found to be significant predictors of perceived program benefits. As a pioneering attempt, this study provides evidence supporting the success of the Tin Ka Ping P.A.T.H.S. Project.

INTRODUCTION

Adolescence is a unique time of life before teenagers step into adulthood [1]. In this transition period, internalizing and externalizing problems are common [2]. Traditionally, adolescent behavioral problems such as delinquency, substance abuse, and violence have attracted much attention from researchers [1, 3]. With rapid changes in the contemporary world, there is an emergence of new types of adolescent developmental issues such as obesity, eating disorders, unhealthy sexual behaviors, materialization, and low academic motivation [4, 5]. Besides externalizing behaviors, internalizing symptoms also exist [6, 7]. For instance, adolescents' problematic eating behaviors and associated problems (e.g., overweight and obesity) were largely triggered by their weight and body dissatisfaction [8], which in turn probably cause emotional processing difficulties [4]. In the same vein, depressive symptoms, anxiety symptoms, and life stress could also result in unhealthy dietary patterns [9, 10].

Given these rising concerns, prevention and treatment concentrating on one single problem is the common approach in the past to deal with adolescent problematic behaviors and symptoms [11]. However, realizing the co-existence of internalizing and externalizing problems and the overlapping causes, ecological models have been commonly adopted in understanding adolescent developmental issues [12]. Among which, positive youth development (PYD) is an approach that aims to prevent problematic behaviors and symptoms through promoting adolescents' positive development adopting a "whole-person" perspective [13]. PYD contends that adolescents are "resources to be developed" with their strengths in the developmental process [14]. In Western societies, evidence from previous research supported that PYD programs are effective in reducing the probability of adolescent problem behaviors [15, 16].

With particular reference to China, adolescent externalizing behavior continues to rise in the face of complex and ever-changing environment. For example, the latest findings of adolescent sexual behavior study in Hong Kong showed that adolescent sexual behavior and their intention to engage in sexual behavior both gradually increased over time [17]. Similarly, statistics from the National Health and Family Planning Commission in mainland China suggested that the average age for first-time sex behaviors was 15.9, with more than 45 percent of the participants not using contraceptives [18]. Regarding health risk behaviors, findings from China Nationwide Nutrition and Health Survey in 2016 pointed out that adolescent obesity rates are rising dramatically in the last 30 years with prevalence rates of overweight and obese boys increased to 11.1% in 2014 from 0.2% in 1985 [19]. Besides, in the area of unhealthy sleep behavior among adolescents, findings from an eight-year longitudinal study showed that nearly all students experienced at least one type of sleep problems [20]. Another study conducted in southeast China found that the prevalence rate of less-than-5-hours sleep among adolescents (aged 13 to 20) was 5.6% [21]. Meanwhile, short sleep among Chinese adolescents was associated with lower health-related quality of life [22], which are related to defiant attitudes, poor academic performance, and even suicidal ideation and attempts [20, 21]. Although the highly comorbid externalizing and internalizing problems in Chinese adolescents are severe, there are few PYD programs in different Chinese communities, particularly in mainland China.

Utilizing PYD constructs [14] to promote holistic development among Chinese adolescent, Shek and his research team [23] developed a PYD program entitled Project P.A.T.H.S. (Positive Adolescent Training through Holistic Social Programs) for junior secondary students in Hong Kong. Funded by The Hong Kong Jockey Club Charities Trust since 2005, this project has gone through over a decade's implementation [24]. Later on, to benefit adolescents in mainland China, Tin Ka Ping Foundation introduced the Project P.A.T.H.S. in mainland China since 2011 [25], transplanting it into "Tin Ka Ping P.A.T.H.S. Project." With reference to the 15 positive youth development constructs identified by Catalano et al. [7], the research team developed school-based programs attempting to promote adolescent personal qualities (e.g., clear and positive identity, self-efficacy) and various competences (e.g., moral competence, social competence).

With the encouraging outcomes achieved in junior secondary students [26], the Tin Ka Ping P.A.T.H.S. Project was further extended into senior secondary schools since 2014. In response to specific developmental issues in Chinese adolescents, the TKP P.A.T.H.S. Project designed senior curriculum to strengthen the personal abilities and developmental assets among mainland senior secondary students. For example, in Unit EC 5.1 (emotional competence) named "Youth in Full Bloom," through taking part in both individual and group activities, students would learn to recognize different ways of expressing anger and its corresponding consequences, as well as to master effective anger management skills. As the senior curricula-based programs are new to both implementers and participants, the research team is quite concerned about its impact on the students. Thus, it is necessary to test out its effectiveness for further nationwide implementation.

Multiple evaluation methods have been employed to examine the effectiveness of the Project P.A.T.H.S. in Hong Kong since its inception, including objective and subjective outcome evaluation, process evaluation, qualitative assessment, as well as student products that include student reflection diaries and drawings [27]. Longitudinal evaluation findings further confirmed the long-term positive effect of the project in promoting adolescent holistic development. Meanwhile, different stakeholders (e.g., participants, implementers) recognized the effectiveness of the program [24]. Extensive studies have indicated that previous P.A.T.H.S. programs explicitly achieved the whole-person development goals. For example, Shek and Yu [28] found that through participating in Project P.A.T.H.S., adolescents reported a slower rate of increase in sexual behavior. Nevertheless, as the Tin Ka Ping Project is a new project implemented in China, the question of how useful the Tin Ka Ping P.A.T.H.S. Project in nurturing mainland Chinese adolescents needs to be answered. Hence, there is a need to conduct systematic evaluation studies.

Shek et al. [29] pointed out that participants' subjective satisfaction could yield useful information since it is highly associated with the objective PYD attribute scores after program implementation. Therefore, in the present study, subjective outcome evaluation was employed to assess the effectiveness of the Tin Ka Ping P.A.T.H.S. Project. Three dimensions of the program were covered, including perceived program content quality, perceived instructor quality, and perceived benefits of the program. Previous studies have identified factors affecting the effectiveness of school-based programs. Payne and Eckert [30] demonstrated that program structure was the most important factor than program providers and school climate in predicting program implementation quality. However, there is a consensus that teaching quality strongly predicts valued intended learning outcomes [31]. Hence, the importance of factors that predict program effectiveness still needs further investigation.

Against the background mentioned above, several objectives were intrinsic to the current study. First, descriptive profiles on the responses of the participants to the program were presented. Based on past findings, it was predicted that a high proportion (at least 80%) of the respondents would show positive responses (Hypothesis 1). Second, the association among these three dimensions of subjective outcome evaluation was investigated. Based on previous findings, we predicted that there would be significant correlations amongst the three dimensions of subjective outcome evaluation (Hypotheses 2a to 2c). Third, the predictive effects of students' satisfaction with program content and instructor quality on perceived program benefits were examined. It was predicted that both perceived program quality and implementer would predict perceived program effectiveness (Hypotheses 3a and 3b). Finally, grade differences in participants' subjective evaluation on different indicators were also analyzed. Based on previous findings [32], it was expected that Grade 10 students would have more satisfaction than did Grade 11 students (Hypothesis 4).

OUR STUDY

In the 2015-2016 academic year, a total of 20,358 students from 30 schools participated in the Tin Ka Ping P.A.T.H.S. Project. Among which, 5,784 participants were senior secondary students from 17 schools, locating in both developed areas like Shanghai, Jiangsu and underdeveloped area like Gansu, and Guizhou. With encouraging findings in the initial implementation [26], the research team collected feedback from six participating schools. Correspondingly, the current study examined participants' perceptions of the effectiveness of the Tin Ka Ping P.A.T.H.S. senior secondary program in the 2015-2016 academic year.

After one year, all students were invited to respond to a subjective outcome evaluation form. Research findings in previous studies strongly supported the validity and reliability of this assessment tool [25, 29]. Before the data collection process, participants were informed of the evaluation purpose and confidentiality of the data. With clear guidelines and adequate time to complete the assessment form, participants responded in a self-administration format. A total of 1,762 completed questionnaires were collected from senior students, including 1,433 from Grade 10 and 329 from Grade 11.

Instruments

Adopted from the Subjective Outcome Evaluation Form for participants (Form A) of Project P.A.T.H.S. in Hong Kong, the evaluation form employed in this study used the same wording but translated all items into simplified Chinese characters.

This subjective outcome evaluation form is comprised of three parts. The first part contained three rating scales measuring different aspects: participants' perceptions of the program content using 6-point Likert scale (1 = "strongly disagree"; 6 = "strongly agree") with 10 items, the performance of program instructors with same scale structures covering 10 items, and the perceived program benefits using 5-point Likert scale (1 = "unhelpful"; 5 = "very helpful") with 16 items. The second part employed three extra items to understand participants' overall attitudes (e.g. the willingness to participate in similar courses again in the

future). The last part used four open-ended questions to examine participants' gains and opinions (e.g. the most important things that the participants learned from the program).

The present study only analyzed and investigated the quantitative parts (overall 39 items) of this evaluation form, while participants' responses to the open-ended questions will be discussed elsewhere.

Data Analysis

Findings on the percentages of responses to the program content, instructors' performance, and program benefits as well as their overall satisfaction with the program were analyzed by descriptive statistical analyses in this study. By examining the percentages of responses to each response category, we can generate a picture on the satisfaction of the respondents on the different dimensions of the program.

Reliability analysis was conducted to investigate the internal consistency of the total scale and the subscales. Pearson correlation analysis was performed to examine the inter-relationships amongst the three domains of the program. A multivariate Analysis of Variance (MANOVA) was conducted to find out the differences of the three factors between Grade 10 and Grade 11. Lastly, to determine the predictors of the perceived program benefits, multiple regression analyses were employed. All the analyses were performed using SPSS 23.0.

FINDINGS

A total of 1,762 completed subjective evaluation forms were collected. As presented in Table 1, reliability analysis showed that the total scale and subscales had high internal consistency: 10 items on perceived program content ($\alpha = .94$), 10 items on perceived instructor quality ($\alpha = .96$), 16 items on perceived benefits ($\alpha = .97$), and the overall 36 items measuring program effectiveness ($\alpha = .96$).

Table 1. Reliability analyses and correlations among participants' perceptions on program content, instructors and program benefits

Subjective outcome evaluation Scales	M	SD	Cronbach's alphas	Mean of inter-item correlations	Inter-scale correlation		
					Program content	Program instructors	Program benefits
Program Content	5.25	.78	.94	.60	-	-	
Program Instructors	5.45	.72	.96	.71	.58***	-	
Program Benefits	4.23	.79	.97	.66	.36***	.25***	-
Total Effectiveness	4.86	.59	.96	.39	.77***	.70***	.81***

Note: *** $p < .001$.

Several observations based on descriptive statistical analyses can be highlighted from Tables 2 to 5. First, the findings in Table 2 revealed that over 93% of the participants expressed positive attitudes with all items scored 4 or above; 94.7% of the participants liked this program very much (item 10). Specifically, 96.4% participants recognized the "clear objectives of the curriculum" and 96.1% endorsed that the design of the curriculum was good.

Second, Table 3 indicated that almost all students (97.6% of the participants) held positive views of the implementers (item 10) and they agreed that the instructors were well-prepared for class (97.9%). Almost all students also felt that the instructors were ready to help students. Regarding perceived program effectiveness (Table 4), 95.2% of the participants agreed that the program was able to promote their overall development, including improvement in “self-awareness” (95.7%), “ability to distinguish between good and bad” (95.2%), and “ability to face the future with a positive attitude” (95.1%). Table 5 further shows that 95.2% of the participants would potentially “recommend this program to their peers,” 94.4% would consider “to join the similar program again,” and 98.0% were satisfied with this program as a whole. In short, Hypothesis 1 was supported.

Consistent with our prediction, Pearson correlation analyses (Table 1) suggested that there was a strong relationship between perceived program content and perceived instructor quality ($r = .58, p < .001$). Such strong association could also be found in the relationships of these two domains with perceived program benefits (program content: $r = .36, p < .001$; instructor quality: $r = .25, p < .001$). In short, Hypotheses 2a to 2c were supported.

Multiple regression analysis was further performed to examine the predictors of perceived effectiveness. Results in Table 7 revealed that both perceptions of program content ($\beta = .32, p < .001$) and perceived quality of instructors ($\beta = .07, p < .05$) could positively predict perceived program benefits, explaining 8% and 38% of the variance in Grade 10 and Grade 11, respectively. The findings supported Hypotheses 3a and 3b.

Results based on MANOVA (Table 6) showed that significant differences in participants' satisfaction across grades were found for program content, instructor performance, and program benefits ($F = 60.69, 18.86, \text{ and } 56.47, p < .001, \eta^2 = .035, .011, \text{ and } .032$, respectively). In all three dimensions, Grade 10 students reported higher levels of satisfaction ($M = 5.32, 5.49, \text{ and } 4.30$, respectively) compared with Grade 11 students ($M = 4.91, 5.25, \text{ and } 3.90$, respectively). The findings provided support for Hypothesis 4.

Table 2. Descriptive statistics of the participants' evaluations on the program content

Items	Respondents with positive responses (Options 4-6)					
	Grade 10		Grade 11		Overall	
	<i>N</i>	%	<i>n</i>	%	<i>N</i>	%
The objectives of the curriculum are very clear.	1393	97.3	301	92.3	1694	96.4
The design of the curriculum is very good.	1384	96.6	305	93.8	1689	96.1
The activities were carefully planned.	1374	96.0	304	94.1	1678	95.7
The classroom atmosphere was very pleasant.	1367	95.5	300	93.5	1667	95.1
There was much peer interaction amongst the students.	1368	95.5	295	91.0	1663	94.7
I participated actively during lessons (including discussions, sharing, games, etc.).	1372	95.8	289	89.2	1661	94.6
I was encouraged to do my best.	1368	95.5	288	90.0	1656	94.5
The learning experience I encountered enhanced my interest towards the lessons.	1359	94.9	281	86.7	1640	93.4
Overall speaking, I have very positive evaluation of the program.	1363	95.2	291	90.4	1654	94.3
On the whole, I like this curriculum very much.	1372	95.8	292	89.6	1664	94.7

Note: All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Table 3. Descriptive statistics of the participants' evaluations on the program instructors

Items	Respondents with positive responses (Options 4-6)					
	Grade 10		Grade 11		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
The instructor(s) had a good mastery of the curriculum.	1402	98.0	305	93.6	1707	97.2
The instructor(s) was well prepared for the lessons.	1406	98.2	313	96.6	1719	97.9
The instructor(s)' teaching skills were good.	1393	97.4	308	94.8	1701	96.9
The instructor(s) showed good professional attitudes.	1392	97.3	309	94.8	1701	96.8
The instructor(s) was very involved.	1407	98.3	304	94.4	1711	97.5
The instructor(s) encouraged students to participate in the activities.	1393	97.3	310	95.7	1703	97.0
The instructor(s) cared for the students.	1402	97.9	314	96.6	1716	97.7
The instructor(s) was ready to offer help to students when needed.	1401	97.8	313	96.6	1714	97.6
The instructor(s) had much interaction with the students.	1392	97.2	311	95.4	1703	96.9
Overall speaking, I have very positive evaluation of the instructors.	1400	97.8	315	96.6	1715	97.6

Note: All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (Options 4-6) are shown in the table.

Table 4. Descriptive statistics of the participants' evaluations on the program benefits

The extent to which the course (i.e., the program that all students have joined) has helped you:	Respondents with positive responses (Options 3-5)					
	Grade 10		Grade 11		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
It has strengthened my bonding with teachers, classmates and my family.	1345	94.5	292	90.4	1637	93.8
It has strengthened my resilience in adverse conditions.	1336	93.9	291	90.7	1627	93.3
It has enhanced my social competence.	1345	94.5	294	91.6	1639	94.0
It has improved my ability in handling and expressing my emotions.	1358	95.4	295	92.5	1653	94.9
It has enhanced my cognitive competence.	1353	95.1	286	89.4	1639	94.0
My ability to resist harmful influences has been improved.	1362	95.8	293	91.6	1655	95.0
It has strengthened my ability to distinguish between the good and the bad.	1367	96.1	291	91.5	1658	95.2
It has increased my competence in making sensible and wise choices.	1347	94.7	286	89.4	1633	93.7
It has helped me to have life reflections.	1337	94.0	280	87.2	1617	92.8
It has reinforced my self-confidence.	1354	95.2	288	89.4	1642	94.1
It has increased my self-awareness.	1369	96.3	300	93.2	1669	95.7
It has helped me to face the future with a positive attitude.	1360	95.6	299	92.9	1659	95.1
It has helped me to cultivate compassion and care about others.	1345	94.5	290	90.6	1635	93.8
It has encouraged me to care about the community.	1299	91.3	267	83.2	1566	89.8
It has promoted my sense of responsibility in serving the society.	1341	94.6	293	91.3	1634	94.0
It has enriched my overall development.	1364	95.9	296	92.2	1660	95.2

Note: All items are on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (Options 3-5) are shown in the table.

Table 5. Summary of participants' subjective evaluations on other aspects

Items	Respondents with positive responses (Options 3-5)					
	Grade 10		Grade 11		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
Willingness to suggest friends with similar needs or conditions to participate in the program ^a	1381	96.4	294	90.2	1675	95.2
Willingness to participate in similar courses again in the future ^a	1370	95.6	290	89.0	1660	94.4
Satisfaction with this course on the whole ^b	1412	98.5	312	95.4	1724	98.0

Note: ^a: the item is on a 4-point Likert scale with 1 = definitely will not suggest, 2 = will not suggest, 3 = will suggest, 4 = definitely will suggest. Only respondents with positive responses (Options 3-4) are shown in the table.

^b: the item is on a 6-point Likert scale with 1 = very dissatisfied, 2 = moderately dissatisfied, 3 = slightly dissatisfied, 4 = satisfied, 5 = moderately satisfied, 6 = very satisfied. Only respondents with positive responses (Options 4-6) are shown in the table.

DISCUSSION

The purpose of the current study was to explore senior students' evaluation of the Tin Ka Ping P.A.T.H.S. Project in its pilot extension phase. As there is a lack of PYD programs designed for Chinese adolescents and related evaluation attempts are scarce, this study could be regarded as a pioneering attempt.

The current study adds to the Chinese literature in several important aspects. First, the measuring instrument used in this study is a constructive response to the lack of validated evaluation tools in mainland China. Second, the sample size is sufficiently large to permit generalization to other populations. Third, concerning the externalizing and internalizing problems among adolescents [6], positive perceptions of the perceived benefits of the program indicated that the Tin Ka Ping P.A.T.H.S. Project could serve as a protective factor by promoting the psychosocial competence in adolescents [33]. Furthermore, this study further investigated the predictors of perceived benefits, which could make a contribution to the advancement of the theories and applications of PYD programs in mainland China.

Several positive observations support the above-mentioned contributions. First, high values of Cronbach's coefficient and inter-scale correlation among three subscales gave support to the excellent psychometric properties of this subjective outcome evaluation instrument. Second, consistent with the previous findings from an evaluation of Project P.A.T.H.S. in Hong Kong [24], profiles of responses to all items echoed that the majority of senior secondary students participating in the program were fond of this PYD program. A considerable proportion of participants believed that this program has helped them promote different competencies (e.g., cognitive competence, sense of responsibility in serving the society). In particular, quality of the program instructor was more recognized as revealed by the high endorsement rate (97%). Generally speaking, the findings supported Hypothesis 1. In line with other studies, different dimensions of subjective outcome evaluation were significantly correlated (Hypotheses 2a to 2c) and both perceived program quality and implementers were significant predictors of perceived program effectiveness (Hypotheses 3a and 3b). Similar findings also occurred in the evaluation studies on the Project P.A.T.H.S. in Hong Kong [34].

Similar to previous findings, grade differences existed in all three aspects (i.e., program content, instructor quality, and perceived benefits), with Grade 10 students showing more favorable satisfaction ratings. This finding is consistent with a previous study conducted by Shek and Law [34] that Grade 7 students maintained more positive attitudes compared with Grade 8 students.

Table 6. Comparisons of participants' subjective outcome evaluations on different aspects across grades

Subjective outcome evaluation Scales	Grade 10		Grade 11		MANOVA	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>F</i>	η^2
Program Content	5.32	.75	4.91	.83	60.69 ^a	.035

Note: ^a Standardized coefficients. * $p < .05$. ** $p < .01$. *** $p < .001$.

Although this paper presents the first study of subjective outcome evaluation of the Tin Ka Ping Project in China, several limitations of this study are worth mentioning. First, the disparity in sample size between different grades deserves serious consideration before making solid conclusions. Second, senior secondary students in Grade 12 were not involved since they were busy with preparation for examination. However, they are also important targets who may encounter intense challenges physically and mentally in the face of the college entrance examination. Third, as subjective outcome evaluation only provides evidence from one perspective, objective outcome evaluation regarding participants' development in real life situations is also required. Despite these limitations, the positive findings in the present study could be interpreted as evidence supporting the effectiveness of the Tin Ka Ping P.A.T.H.S. Project in mainland China.

ACKNOWLEDGMENTS

The present paper and the Tin Ka Ping P.A.T.H.S. Project are financially supported by Tin Ka Ping Foundation. This chapter is a reprint with minor revisions of an earlier published paper in the *International Journal of Child and Adolescent Health* 2018;11(1) issue with permission.

ABSTRACT

In this chapter we investigated the subjective outcome of a positive youth development program, the Tin Ka Ping project, among secondary school students in two relatively underdeveloped cities in China mainland. A total of 1,573 students who participated in the project responded to an evaluative form upon completion of the project. The findings showed that the majority of the participants were highly satisfied with the project. Regardless of their grade, students consistently rated the program content and the instructors positively, and they perceived the project as beneficial to their personal development in multiple areas. Participants' perceptions about the program content and the instructors both significantly predicted their perceived effectiveness of the project. Similar to previous findings based on adolescents living in economically developed Chinese cities, the present study suggests that the Tin Ka Ping project was equally welcomed by youth in underdeveloped areas in China, and provides evidence for the usefulness of the project in promoting Chinese adolescents' holistic development.

INTRODUCTION

The Project P.A.T.H.S. is a curriculum-based positive youth development program designed for Chinese adolescents in Hong Kong [1]. Adopting a strengths-based approach,

* Corresponding Author's Email: lu.yu@polyu.edu.hk.

the program focuses on promoting the development of 15 well-established positive youth development attributes among youth, including bonding (BO), social competence (SC), emotional competence (EC), cognitive competence (CC), behavioral competence (BC), moral competence (MC), self-efficacy (SE), Prosocial Norms (PN), Resilience (RE), Self-Determination (SD), Spirituality (SP), clear and positive identity (ID), belief in the future (BF), prosocial involvement (PI) and recognition of positive behaviour (RB) [2]. It is believed that by nurturing these attributes, youth behavioral problems, such as delinquency, alcohol use, and Internet addiction, can be effectively prevented [3, 4]. With the fund by The Hong Kong Jockey Club, the project P.A.T.H.S. has been widely implemented in secondary schools in Hong Kong since 2006, to promote adolescents' holistic development. So far, a total of 280 secondary schools with more than 200,000 students in Hong Kong have participated in the project. To examine the effectiveness of the program, multiple evaluative strategies have been adopted and the findings converged to suggest that the project P.A.T.H.S. was well received by different stakeholders, and had significant impact on Hong Kong adolescents' development [1, 5-7].

The success of the project P.A.T.H.S. in Hong Kong has provided evidence for the applicability and effectiveness of using positive youth development approach to promote Chinese adolescents' development. However, such program is almost non-existent in China mainland, although it has the largest youth population in the world. In particular, the rapid economic and social development that has recently taken place in the country has significant influence on adolescent psychological well-being. A recent review of the current status of youth mental health in China mainland showed that adolescent behavioral problems, mood disorders, substance use, and youth suicide are all on the rise [8]. Besides, similar to Hong Kong youth, adolescents in China mainland are facing a wide range of developmental issues [9, 10], which could lead to various risk behaviors and problems, if not handled well [11]. For example, Chinese parents' high expectation on their children's academic performance and the increased competition have created high academic stress in adolescents. According to a survey by China Youth Social Service Centre, around 70% of secondary school students considered academic stress as their major source of pressure [12]. In another study, perceived academic stress was found to significantly predict high school students' depressive symptoms, while this relationship could be moderated by positive school climate with low level of achievement orientation [9]. This suggests that promoting a healthy school culture or nurturing positive values among students regarding achievement may effectively prevent their mental health problems even the academic stress remains. These findings point to the pressing need of developing and implementing effective prevention and intervention programs to help Chinese young people tackle with the challenges and have healthy holistic development. Positive youth development program, like the Project P.A.T.H.S., may serve this purpose.

Against this background, with the financial support of the Tin Ka Ping foundation, the research team of the project P.A.T.H.S. started to adapt the project for Chinese young people since 2010, collaborating with a university in China mainland. The new project, entitled the Tin Ka Ping (TKP) project, was developed based on the theoretical framework of P.A.T.H.S., whereas took into account the specific cultural context in China Mainland [4]. The project was first piloted in four secondary schools in East China and then further promoted and formally implemented in 30 secondary schools across 27 cities in China [4]. A series of training sessions were provided to school teachers and social workers by the research team before the program implementation to ensure the quality of implementation. To evaluate the

effectiveness of the TKP project, similar evaluative studies were conducted. Both qualitative and quantitative findings supported that the TKP project was highly welcomed by teachers and students, and effectively promoted Chinese secondary school students' positive development [13-17].

While the TKP project has been offered in a number of Chinese cities with different economic backgrounds, evaluative studies were mainly conducted in schools located in relatively developed areas, such as Shanghai, and its nearby cities like Suzhou and Yangzhou [4]. There is a lack of research investigating the implementation quality and outcomes of the project for students in underdeveloped regions where educational resources are relatively limited as compared to big cities. Therefore, the present study aimed to examine the effectiveness of the TKP project for adolescents in two underdeveloped Chinese cities: Baiyin and Shaoguan. Both cities are characterized as “countdown” cities with declined population and economy in recent years. Baiyin used to be a prosperous city with abundant mineral resources, but its development has been slowing down as the mines are exhausted, and the local economy gradually declines. Another city, Shaoguan, had been famous for its steel, non-ferrous metal, electric power, machine, tobacco, pharmaceutical and toy industries. However, since 1980s, the industry development in Shaoguan became tardy and the city has been deindustrialized. These socio-economic changes have inevitably affected local people's life satisfaction, feeling of happiness and mental health [18-20], which may further influence the development of local youth, as well as the implementation and effectiveness of the TKP project in these areas. However, although the TKP project has been implemented in two secondary schools in the two cities for three years, it remains unclear whether the curriculum content of the project is appropriate for local adolescents, whether the project implementers, i.e., school teachers, are able to implement the project with high quality, and to what extent students perceive the project as beneficial to their development.

The present study was designed to address these questions through investigating students' perceptions about the project in two participating schools in Baiyin and Shaoguan. Specifically, we intended to 1) examine participant's subjective outcome evaluation about the TKP project in terms of their views on the program content, instructors and benefits; 2) to compare subjective outcome evaluations among students of different grades and 3), to investigate the predictive effects of students' perceptions about the program quality, the implementers, and benefits of the program on their overall satisfaction of the program.

OUR STUDY

Participants of the present study were recruited from students of two secondary schools in Baiyin (one school) and Shaoguan (one school) who joined the TKP project in the academic years of 2015/16 and 2016/17. Secondary 3 and 6 students (equivalent to Grade 9 and 12) didn't participate because of their heavy workload for the preparation of the entrance exams to high school and university. At the participating school in Baiyin, the program was implemented for senior students at Secondary 4 and 5 only (equivalent to Grade 10 and 11), while at the school in Shaoguan, the program was offered to both junior and senior students in Secondary 1, 2, 4, and 5 (equivalent to Grade 7, 8, 10, and 11).

After obtaining written consents from the school management, students, and their parents, all participating students completed a subjective outcome evaluation form on a voluntary

basis upon completion of the project. The survey was administered by trained program workers in classroom settings with standardized instructions. Students were reassured about the confidentiality and anonymity of their responses. A total of 1,573 participants completed the questionnaires, including 481 students at Secondary 1 (only Shaoguan), 468 students at Secondary 2 (only Shaoguan), 392 students at Secondary 4 (173 from Baiyin, and 219 from Shaoguan), and 232 students at Secondary 5 (142 from Baiyin and 90 from Shaoguan).

Instruments

A validated subjective outcome evaluation form was used to assess students’ perceptions about the TKP project. The form is consisted of six parts. The first subscale contains 10 items measuring participants’ subjective evaluation about the program content. The second part also has 10 items but focusing on participants’ perceptions about the program instructors. Items of both subscales were rated on a 6-point Likert scale (1 = strongly disagree, 6 = strongly agree). The third part measures students’ perceived benefits of the project, consisted of 16 items evaluated on a 5-point rating scale (1 = unhelpful, 5 = very helpful). The fourth part has two questions asking 1) whether the participant would recommend the project program to their friends, and 2) whether the student would like to attend a similar program in the future. The fifth part asks students’ overall satisfaction about the program based on a 6-point rating scale (1 = strongly dissatisfied; 6 = strongly satisfied). The final part is consisted of four open-ended questions about students’ other experiences in the project, and the related findings would be reported elsewhere. The evaluation form shows good internal consistency on the present sample of students. As displayed in Table 1, Cronbach’s alpha coefficients for the three subscales were all above .92, and mean inter-item correlations ranged between .52 and .65.

Table 1. Reliability analyses and correlations among participants’ perceptions on program content, instructors, and program benefits

Subscales	M	SD	Cronbach’s α	Mean inter-item correlations	1	2
Views about program content	4.84	.79	.92	.52	-	-
Views about instructors	5.11	.79	.95	.65	.45***	-
Perceived program benefits	3.84	.79	.94	.57	.36***	.31***

Note: *** $p < .001$.

Data Analyses

Descriptive statistics were used to depict students’ subjective outcome evaluation about the TKP project. Particularly, percentages of students with positive ratings were summarized in terms of their views about program content, program implementers/instructors, and perceived benefits. To compare students’ subjective outcomes across grades, Multivariate Analysis of Variance (MANOVA) was conducted with participants’ perceptions about program, perceptions about instructors, and perceived benefits of the project as three dependent variables, and students’ grade as the independent variable. Lastly, to determine the

predictive effects of students' perceptions of program content and instructors on students' perceived benefits of the program, multiple regression analyses were conducted. In the model, perceived program benefits served as the dependent variable, students' grade, perceptions about the program content, and views about instructors served as three independent variables. All the analyses were performed using SPSS 23.0.

FINDINGS

Means and standard deviations of students' subscale scores were summarized in Table 1. Tables 2 to 5 further report the percentages of students with positive responses to different aspects of the project. First, the majority of students had positive ratings on the program content. As can be seen in Table 2, students of different grades consistently showed favorable evaluation about various aspects of the program content. For instance, 92.3% of students at Secondary 1, 88.5% of students at Secondary 2, 92.6% and 86.6% of the Secondary 4 and 5 students agreed that they liked the curriculum very much. Based on the whole sample, more than 92% of the participants expressed that "the design of the curriculum is very good", and that "the activities were carefully planned"; 89.3% of the participants reported that they participated actively during lessons and "have very positive evaluation of the program". Second, in terms of participants' evaluation about the program instructor, the percentage of students with positive ratings was overwhelmingly high (see Table 3). More than 93% of the students perceived the instructors as having a good mastery of the curriculum (93.8%), being well prepared for the lessons (93.4%), having good teaching skills (93.4%), and showing good professional attitudes (93.6%). Students also appreciate teachers' encouragement and care for the students. Over 95% of the participants agreed that the instructor was ready to offer help when needed, and had very positive evaluation of the instructors.

Table 2. Percentage of participants with positive ratings on program content

Items	Respondents with positive responses (Options 4-6)									
	Secondary 1		Secondary 2		Secondary 4		Secondary 5		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
The objectives of the curriculum are very clear.	450	93.6	444	94.9	367	93.6	211	90.9	1472	93.6
The design of the curriculum is very good.	442	91.9	438	93.6	365	93.1	213	91.8	1458	92.7
The activities were carefully planned.	443	92.1	424	90.6	369	94.1	212	91.4	1448	92.1
The classroom atmosphere was very pleasant.	404	84.0	426	91.0	363	92.6	215	92.7	1408	89.5
There was much peer interaction amongst the students.	424	88.1	426	91.0	350	89.3	210	90.5	1410	89.6
I participated actively during lessons (discussions, sharing, games, etc.).	430	89.4	425	90.8	346	88.3	203	87.5	1404	89.3
I was encouraged to do my best.	416	86.5	410	87.6	343	87.5	202	87.1	1371	87.2
The learning experience I encountered enhanced my interest towards the lessons.	435	90.4	412	88.0	358	91.3	196	84.5	1401	89.1
Overall speaking, I have very positive evaluation of the program.	426	88.6	416	88.9	349	89.0	208	89.7	1404	89.3
On the whole, I like this curriculum very much.	444	92.3	414	88.5	363	92.6	201	86.6	1422	90.4

Note: All items are on a 6-point Likert scale with 1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = slightly agree, 5 = agree, 6 = strongly agree. Only respondents with positive responses (options 4-6) are shown in the table.

Table 3. Percentage of participants with positive ratings on program instructors

Items	Respondents with positive responses (Options 4-6)									
	Secondary 1		Secondary 2		Secondary 4		Secondary 5		Overall	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>N</i>	%
The instructor(s) had a good mastery of the curriculum.	446	92.7	446	95.3	370	94.4	213	91.8	1475	93.8

It has strengthened my resilience in adverse conditions.	413	85.9	418	89.3	369	94.1	202	87.1	1402	89.1
It has enhanced my social competence.	424	88.1	418	89.3	366	93.4	214	92.2	1422	90.4
It has improved my ability in handling and expressing my emotions.	427	88.8	421	90.0	368	93.9	214	92.2	1430	90.9
It has enhanced my cognitive competence.	422	87.7	423	90.4	372	94.9	209	90.1	1426	90.7
My ability to resist harmful influences has been improved.	427	88.8	438	93.6	372	94.9	208	89.7	1445	91.9
It has strengthened my ability to distinguish between the good and the bad.	434	90.2	439	93.8	369	94.1	207	89.2	1449	92.1
It has increased my competence in making sensible and wise choices.	430	89.4	411	87.8	365	93.1	206	88.8	1412	89.8
It has helped me to have life reflections.	409	85.0	409	87.4	361	92.1	199	85.8	1378	87.6
It has reinforced my self-confidence.	422	87.7	403	86.1	362	92.3	204	87.9	1391	88.4
It has increased my self-awareness.	420	87.3	419	89.5	371	94.6	210	90.5	1420	90.3
It has helped me to face the future with a positive attitude.	423	87.9	437	93.4	367	93.6	209	90.1	1436	91.3
It has helped me to cultivate compassion and care about others.	422	87.7	416	88.9	365	93.1	210	90.5	1413	89.8
It has encouraged me to care about the community.	374	77.8	375	80.1	356	90.8	200	86.2	1305	83.0
It has promoted my sense of responsibility in serving the society.	413	85.9	418	89.3	368	93.9	212	91.4	1411	89.7
It has enriched my overall development.	436	90.6	442	94.4	371	94.6	206	88.8	1455	92.5

Note: All items are on a 5-point Likert scale with 1 = unhelpful, 2 = not very helpful, 3 = slightly helpful, 4 = helpful, 5 = very helpful. Only respondents with positive responses (options 3-5) are shown in the table.

Third, Table 4 reports students' perceived benefits of the project. As shown in the table, 92.5% of the participants agreed that the program has enriched their overall development, 91.3% of the participants perceived that the program helped them to face the future with a positive attitude, and 92.1% of the participants reported that the programme has strengthened their ability to distinguish between the good and the bad. Moreover, Table 5 indicates that 94.8% of the participants were willing to recommend their friends to participate in this program and 92.9% of the participants would consider joining a similar program in the future. The overall satisfaction was also high, with 95.3% of the participants expressing that they were satisfied or very satisfied with the project as a whole. Overall speaking, these findings suggest that the TKP project has been welcomed by adolescents in Baiyin and Shaoguan, which provide positive evidence for the successful implementation of the project underdeveloped regions.

Table 5. Percentage of participants with positive ratings on other aspects of the program and overall satisfaction

Items	Respondents with positive response (options 3-5)									
	Secondary 1		Secondary 2		Secondary 4		Secondary 5		Overall	
	n	%	n	%	n	%	n	%	N	%
1. Willingness to suggest friends with similar needs or conditions to participate in the program ^a	450	93.6	449	95.9	376	95.9	216	93.1	1491	94.8
2. Willingness to participate in similar courses again in the future ^a	449	93.3	436	93.2	364	92.9	213	91.8	1462	92.9
3. Satisfaction with this course on the whole ^b	449	93.3	451	96.4	381	97.2	218	94.0	1499	95.3

Note: ^aThe two items are rated on a 4-point scale with 1 = definitely will not suggest, 2 = will not suggest, 3 = will suggest, 4 = definitely will suggest. Only respondents with positive responses (options 3-4) are shown in the table.

^bThe item is rated on a 6-point scale with 1 = very dissatisfied, 2 = moderately dissatisfied, 3 = slightly dissatisfied, 4 = satisfied, 5 = moderately satisfied, 6 = very satisfied. Only respondents with positive responses (options 4-6) are shown in the table.

Table 6. Comparisons of participants' subjective outcome evaluations across grades

Subscales	Secondary 1		Secondary 2		Secondary 4		Secondary 5		Tests of Between-Subjects Effects		
	M	SD	M	SD	M	SD	M	SD	F	p	Partial η^2
Views about program content	4.83	.83	4.82	.68	4.86	.84	4.84	.87	0.12	.95	.00
Views about instructors	5.14	.79	5.12	.70	5.05	.86	5.16	.82	1.14	.33	.00
Perceived program benefits	3.84	.84	3.76	.70	3.93	.77	3.84	.89	3.26	.01	.01

Ratings by Students of Different Grades

To compare students' ratings across grades, MANOVA was employed and the results showed a significant multivariate effect for the three dependent variables as a group in relation to students' grade, $F(9, 3765.14) = 2.02$, $p = .03$, Wilk's lambda = 0.99. As seen in Table 6, univariate analyses further suggest that the effect of grade was only significant for students' perceived benefits of the project, but not for their perceptions about program content

and instructors. Post hoc tests revealed that students at Secondary 4 had significantly higher ratings on perceived program benefits than students of Secondary 2 ($p = .01$). No significant differences were detected among students of other grades. It seemed that participants at Secondary 4 level perceived the TKP project as more beneficial to their development than did students of Secondary 2. Overall speaking, the findings suggest that students of different grades had generally consistent ratings about the TKP project.

Prediction of Students' Perceived Benefits

Person correlation coefficients among subscales were reported in Table 1. As expected, participants' views about program content, instructors, and perceived benefits were moderately and positively correlated with each other (r s ranged between .31 and .36, $p < .001$) in expected directions. High ratings of the program content and implementers were significantly associated with high level of perceived benefits of the program. Results of multiple regression analysis further showed that after controlling for the effects of grade ($\beta = .04$, $p = .12$), both students' views about program content ($\beta = .27$, $p < .001$) and their perceptions about the instructors ($\beta = .19$, $p < .001$) significantly predicted project benefits. The two predictors explained 15.9% of the variance in students' perceived benefits of the project, $F(2, 1549)_{\text{change}} = 146.60$, $p < .001$.

DISCUSSION

The aim of this study is to examine whether the TKP project can be well implemented in relatively underdeveloped cities in mainland China to promote positive development of local adolescents, based on subjective outcome evaluation. Using data collected in two years, the findings suggest that the vast majority of the participants perceived the program content positively and had favorable views about the program implementers. Students viewed the project as being beneficial to their development in multiple areas, and expressed their willingness to attend similar programs in the future and to recommend the program to other young people. More than 95% of the participants were satisfied with the project on the whole. These findings support the applicability of positive youth development program in different Chinese contexts [13, 14], and provide preliminary evidence for the effectiveness of the TKP project in promoting adolescents' development in less developed Chinese cities.

Consistent with findings based on secondary school students in Hong Kong and in other Chinese metropolis [15], the current sample of participants showed very positive attitude towards both program content and instructors. Aside from the reason that the TKP project was adapted from a successful youth program with evident outcomes (the project P.A.T.H.S.), the desirable feedbacks from students may also be due to the systematic training conducted by the research team for program implementers [21]. Before each school formally launches the TKP project, the school teaching team is required to attend a series of intensive training workshops in which the theoretical framework of the project, lesson plans for each topic, previous evaluative methods and findings, were introduced by experienced researchers and teachers, through experiential learning and various interactive teaching approaches. The

research team also spent time to discuss with program implementers on the appropriateness of the curriculum content, the pedagogy, and possible difficulties in teaching specific topics. Necessary adaption of the teaching content would be made based on the discussion between researchers and the school teacher. In addition, similar to the project P.A.T.H.S. in Hong Kong, a co-walker scheme has been incorporated in the implementation of the TKP project. For each school, at least one scholar from the research team serves as the co-walker, who keeps constant communication with the school teaching team and provides advice throughout the program implementation in the particular school. All these strategies help the instructors to have extensive preparation and teach the curriculum with confidence, which may contribute to the successful implementation of the project [22]. This also echoes our finding that students' views about the program content and about the instructors significantly predicted their perceived effectiveness of the program.

When we compare students' evaluation across different grades, no significant differences were identified, except that students of Secondary 4 appeared to be more positive when rating the perceived program benefits than did students of Secondary 2. One possible reason may be that Secondary 4 students just successfully passed the entrance exams to high school. These students may have less academic stress and are able to participate in the project more actively than Secondary 2 students who remain facing the problem of entering a high school. It should be noted that as the effect size was quite small (partial $\eta^2 = 0.01$), the finding needs to be further validated in the future based on a larger sample of participants. Generally, students at different grades consistently showed favorable perceptions about the program.

While the findings are encouraging, several limitations of the study must be acknowledged. First, although the sample size of the present study was not small, the participants were from only two schools of the two cities, which may affect the generalizability of the findings. In the future, when the project is implemented on a larger scale, a more representative sample of students from different grade and schools shall be recruited to participate in the evaluation study. Second, this study only gathered student's opinions and did not collect feedbacks from other stakeholders, such as program implementers, other school personnel, and parents. Data provided by other informants on the effectiveness of the project would triangulate the subjective evaluation findings based on students, and offer new insights for researchers to understand the program implementation and its outcomes [23]. Third, apart from the subjective evaluation indicators, more objective outcomes should be measured in the future to evaluate the impact of the program on adolescents' real development [13]. For example, whether students' perceived stress, anxiety, and depression reduced, and their life satisfaction and happiness increased after participating in the program, could be investigated in further studies. Last but not least, other evaluative methods, such as individual interview, focus groups, and reflective journals [16] could be adopted to gain a deeper understanding about how the project plays a role in youth life and helps an adolescent to develop.

To conclude, the present study provides preliminary evidence on the successful implementation of the TKP project in two secondary schools located in less developed regions in China. As there is a lack of evaluation findings focusing on the effectiveness of positive youth development program for Chinese adolescents in these areas [24], the present study makes a useful contribution to the field. The findings suggest that although the positive youth development approach was originally developed in the West [3], it can be well applied in different Chinese contexts to promote the holistic development of adolescents. With the

present evidence, we advocated that more youth programs based on positive youth development approach could be designed and implemented to benefit more Chinese young people.

Chapter 329

**SUBJECTIVE OUTCOME EVALUATION OF A
SERVICE LEADERSHIP SUBJECT:
FINDINGS BASED ON UNIVERSITY STUDENTS
IN HONG KONG**

Janet T. Y. Leung*, PhD

and Daniel T. L. Shek, PhD, FHKPS, BBS, SBS, JP

Department of Applied Social Sciences, The Hong Kong Polytechnic University,
Hung Hom, Hong Kong, PR China

ABSTRACT

In this chapter we assessed the subjective outcome evaluation of a credit-bearing subject entitled “Service Leadership” in a university in Hong Kong. The samples included 64 and 74 students who took the subject offered in the regular semester (Semester 1) and intensive summer semester (Semester 3) in 2016-2017 academic year, respectively. Students’ perceptions of the course content, instructor quality, benefits and global satisfaction of the subject were assessed at the end of the subject. Results indicated that majority of students had positive views toward course content, instructor quality, and benefits from the subject in enhancing their competencies in different aspects, such as social and emotional competence, self-confidence, resilience, and self-leadership. The two delivery modes (i.e., regular semester and intensive summer semester) also showed significant differences in the subjective outcomes, with the course conducted in regular term having higher scores than the course offered in summer term. As predicted, course content, instructor quality, and course benefits were inter-correlated significantly. While course content and instructor quality significantly predicted perceived subject benefits, course content and perceived benefits of the subject were significant predictors of students’ global satisfaction.

INTRODUCTION

One may ask the question: why does a university teach “service leadership”? There are strong reasons to address the question. First, service-oriented industries are the skeleton of the Hong Kong economy, contributing to 92.4% of Gross Domestic Product (GDP) in 2017 in Hong Kong [1]. Among the service industry components, import/export wholesale and retail trades, finance and insurance, and public administration, social and personal services cover 21.5%, 18.9% and 18.2% of the GDP respectively [1]. As university graduates have potential tendency to be engaged in frontline and supervisory positions in these industries, service leadership education is important for preparing the students to contribute to these service industries. Second, Hong Kong is a metropolitan city where people from all over the world come in and out for business, vacation, education and other matters. Other than acquiring the discipline-related knowledge and skills, university students should build up a global perspective and develop the 21st Century skills to adapt to the dynamic environment in the service industries [2]. Dede [2] highlighted four areas of competence in economic and social ecology of the 21st Century, namely: 1) global awareness; 2) economic and entrepreneurial literacy; 3) awareness of civic rights and responsibilities; and 4) health and wellness sensitivity. Besides, the 21st Century skills cover three sets of competency skills, including: learning and thinking skills (e.g., skills on problem-solving, communication, innovation, critical analyses, collaborative learning), information and communications technology (ICT) literacy, and life skills (e.g., leadership, social responsibility, adaptability, self-direction etc.) [2].

Third, service leadership education serves as a platform for building interpersonal and intrapersonal competencies of university students [3, 4], who are at the developmental transition from adolescence to adulthood. During emerging adulthood, individuals need to develop financial independence, shoulder civic responsibilities, establish connections with peers and romantic partners, and build up engagement with work and education [5]. Service leadership education, which focuses on psychosocial competencies, character strengths and caring disposition, may foster positive youth development of university students in their life transition to adulthood [4].

Fourth, young people nowadays face different developmental and ecological challenges in adapting to the competitive and complex environment [6]. Particularly, millennials growing up in a relatively prosperous and protective era are portrayed as egocentric, narcissistic and unempathetic [7]. Also, the rise of materialism has shifted one’s values from concentrating on intrinsic motives (e.g., purpose in life, satisfaction from helping others) to extrinsic ones (e.g., money, prestige) [8]. Hence, there is a need to reinforce the emphases in service leadership (including moral competence, character strengths, caring disposition) in university education, and give students more opportunities to reflect on their own life expectations and values.

Most importantly, university students are important stakeholders of Hong Kong future. They are expected to lead and contribute to the future social and economic development of Hong Kong. Thus, there is an urgent need to nurture the development of university students via service leadership education.

Table 1. Course content of “Service Leadership” subject

Lecture	Topic	Content
1	Introduction	• Overview of the subject • Definitions and conceptions of service leadership • Importance of service leadership in the global world • Relevance to university students
2	Core beliefs and components	• Core beliefs about service leadership
3	Intrapersonal competences	• IQ, EQ, AQ and SQ
4	Interpersonal competences	• Communication, relationship building, conflict resolution
5	Character strengths	• Moral character; basic character strengths
6	Caring disposition	• Social cognition (warmth and competence); primary elements of care (love, listening, and empathy)
7	Character strengths in Chinese philosophies	• Relevance of Confucian virtues to service leadership, e.g., integrity (lian), loyalty (zhong), filial piety (xiao), benevolence (ren) etc.
8	Contemporary leadership models and the dark side of leadership	• Review of contemporary models of leadership • Dark side of leadership
9	Factors leading to positive social relationship	• Trust, fairness, respect, care, behavioral consistency and loyalty
10	Self-leadership	• Self-monitoring, self-regulation, and self-improvement
11	Developmental assets	• Self-esteem; self-efficacy; purpose in life, and optimism about future
12	Review of Service Leadership qualities	• Comparisons between models of leadership • Potential application
13	Wrap-up; Group presentation	• Group presentation

In 2012, the Victor and William Fung Foundation and the Hong Kong Institute of Service Leadership and Management (HKI-SLAM) initiated the Fung Service Leadership Initiative in eight universities in Hong Kong that were funded by the University Grants Council. The Initiative aims at designing and implementing service leadership education courses and programs to university students. Employing a holistic positive development approach, it is expected that service leadership education can help to enhance leadership mentality, values and competencies among university students [9]. As suggested by Shek and Chung [10], the ultimate goal of service leadership education is to promote students' service leadership attributes in order to “maintain Hong Kong's competitiveness in the global market and to develop leaders with a human face” (p. xix).

Adopting the SLAM framework on the main components of service leadership (i.e., relevant task management capabilities, character strengths and a caring personality) [10, 11], The Hong Kong Polytechnic University has designed and implemented a credit-bearing “Service Leadership” subject for undergraduate students. The program consists of 13 lectures highlighting the important attributes of service leadership (see Table 1). Prior studies showed that participants had positive views on course content, instructors, benefits and global satisfaction [12-14]. To replicate previous findings, this study attempted to evaluate the effectiveness of “Service Leadership” subject offered to undergraduate students in a regular semester (Semester 1) and summer semester (with intensive teaching) of the 2016/17 academic year at The Hong Kong Polytechnic University. A subjective outcome evaluation approach was adopted to examine students' perception of (1) course content, (2) course implementers, (3) course benefits; (4) global satisfaction after completing the subject. There are five research questions:

- 1) What are the perceptions of the students on course content, implementers, benefits and global satisfaction after taking the subject?
- 2) Are there any differences in perceptions of course content, implementers, benefits, total effectiveness (combination of perceived course content, implementers and benefits) and global satisfaction between participants taking the subject in the regular semester (Semester 1) and intensive summer semester (Semester 3)? As the subject schedule offered in intensive summer semester is tight, it was hypothesized that participants taking the subject in the regular semester would have a more positive view on course content, implementers, benefits, total effectiveness and global satisfaction than those taking the subject in summer semester (Hypotheses 2a to 2e).
- 3) What are the interrelationships among perceptions of course content, course implementers, course benefits, total effectiveness and global satisfaction of participants of the subject? Based on the results of previous studies [12-14], it was hypothesized that perceived course content, course implementers, course benefits, total effectiveness and global satisfaction of participants would be interrelated with each other (Hypotheses 3a to 3j).
- 4) Do perceptions of course content and implementers predict perceived benefits of the participants? Based on the findings of previous studies [12-14], it was hypothesized that perceptions of course content and implementers of the participants would positively predict their perceived benefits respectively (Hypotheses 4a and 4b).
- 5) Do perceptions of course content, implementers and benefits predict global satisfaction of the participants? Based on the findings of previous studies [12], it was hypothesized that perceptions of course content, implementers, and benefits of the participants would positively predict their global satisfaction respectively (Hypotheses 5a to 5c).

OUR STUDY

The data was collected from the participants of two classes of “Service Leadership” subject offered in regular semester (Semester 1) and intensive summer semester (Semester 3) of 2016-2017 academic year. There were 64 and 74 university students enrolled into the subject during Semester One and intensive summer term, respectively. Written informed consent from students was obtained at the beginning of the course. The students were invited to fill out the Subjective Outcome Evaluation Scale that contained the measures during the last lecture of the course in an anonymous matter. The students were given adequate time to complete the evaluation form. A trained research assistant was responsible to conduct the evaluation, with the absence of the instructor.

Measures

A validated Subjective Outcome Evaluation Scale (SOES) was employed in the present study. The SOES consists of five parts: program content (PC), program implementer (PI), program benefits (PB), global satisfaction of the course and qualitative feedback of the course for further improvement. The present study focused on the first four parts of the SOES.

- 1) Program Content (PC) consists of 10 items, which assesses perceptions of students on course design, in-class activities, interactions among classmates, students' participation and global satisfaction on program content. The items are rated in a 5-point Likert scale on from 1 = "Strongly disagree" to 5 = "Strongly agree." A higher mean score of PC indicates a more positive view of program content from the students.
- 2) Program Implementer (PI) contains 10 items, which measures the students' perceptions of the attitudes, teaching strategies and skills of the instructors, engagement and interactions with the students, as well as global satisfaction on the instructors' teaching. The items are rated on a 5-point Likert scale on from 1 = "Strongly disagree" to 5 = "Strongly agree." A higher mean score of PI indicates a more positive view of program implementer from the students.
- 3) Program Benefits (PB) consists of 18 items, which assesses the students' perceptions of their changes on relevant task competencies (e.g., problem-solving, cognitive competence), care and compassion towards others, qualities of self-leadership and sense of civic responsibility. The items are rated in a 5-point Likert scale on from 1 = "Strongly disagree" to 5 = "Strongly agree." A higher mean score of PB indicates more benefits perceived by the students after participating in the course.
- 4) Global Satisfaction (GS) includes three questions on whether the participants will recommend their friends to select this course, whether they will enroll in similar course again in the future, and their rating of their global satisfaction of the course. For the first two questions of GS, the respondents are requested to rate in a 5-point Likert scale on from 1 = "Definitely will not" to 5 = "Definitely will." Finally, the last question of GS is rated in a 5-point Likert scale on from 1 = "Very dissatisfied" to 5 = "Very satisfied."

Data Analyses

Descriptive data analyses were performed to assess the perceptions of participants on their comments of program content (PC), program implementer (PI) and benefits from the course (PB). A composite variable of "Total Effectiveness" (TE) was created by averaging the scores of all items of PC, PI and PB. One-way ANOVAs were employed to compare between the participants' responses in two semesters. Correlation analyses were performed to examine the interrelationship of the 5 domains (PC, PI, PB, GS and TE). Finally, multiple regression analyses were conducted to assess the relative importance of different domains in affecting perceived benefits and global satisfaction of the participants respectively.

FINDINGS

Regarding program content, the mean score of perceived program content (PC) of total participants was 4.04 (SD = .46) (see Table 2). Most participants of the two classes showed positive responses (Options 4 and 5) on curriculum design, classroom atmosphere, class activities, peer interaction and their own involvement respectively (Table 3). Particularly, the

clear course objectives, content design, classroom activities and interactions among peers were greatly appreciated by the students, with 91.3%, 87.7%, 88.4% and 87.7% of the participants rated positively on the relative items respectively. Overall, 89.9% of the participants showed very positive evaluation on the course, and 82.6% of the participants liked the course very much (see Table 3).

For students' perceptions of program implementer, the results showed very positive responses (Options 4 and 5) on the qualities of instructors, including their knowledge on service leadership, preparation, professional attitudes and involvement (see Table 4). Besides, the instructors showed positive engagement with the students by expressing their care, offering their help, giving encouragement to them, and facilitating interactions among students (see Table 3). Overall, 97.1% of total students from these two classes expressed a very positive evaluation on the instructors (see Table 4). The mean score of perceived program implementer (PI) of total participants was 4.33 (SD = .42), showing participants' positive responses on the program implementers (see Table 2).

Regarding students' perceptions of their benefits from the course, the participants showed positive views (Options 4 and 5) that the course enhanced their situational task competencies, care and compassion towards others, qualities of self-leadership and sense of responsibility to contribute to the society (see Table 5). 86.2% of the total respondents showed that the course promoted their overall development. Besides, the theories, research and concepts helped majority of students understand (88.4% of the students rated Options 4 or 5) and synthesize (89.1% of the students rated Options 4 or 5) the characteristics of successful service leaders (see Table 5). The mean score of perceived program benefits (PB) of total participants was 4.02 (SD = .47) (see Table 2), showing evidence of positive benefits perceived by the students after participating in the course.

On the whole, 86.3% of the students felt satisfied with the subject (Options 4 and 5; see Table 6). 78.3% of the students would invite their friends to enroll in the course, and 57.2% of the students would attend similar courses in the future (see Table 6). The mean score of global satisfaction (GS) of total participants was 3.90 (SD = .67) (see Table 2).

8. It has helped me face the future with a positive attitude.	4.23	.64	57	89.1	3.88	.64	58	78.4	4.04	.66	115	83.3
9. It has enhanced my love for life.	4.03	.67	53	82.8	3.69	.64	46	62.2	3.85	.67	99	71.7
10. It has helped me explore the meaning of life.	4.05	.65	54	84.4	3.69	.60	48	64.9	3.86	.65	102	73.9
11. It has enhanced my ability of self-leadership.	4.33	.56	61	95.3	3.85	.66	54	73.0	4.07	.66	115	83.3
12. It has helped me cultivate compassion and care for others.	4.19	.61	57	89.1	3.89	.61	60	81.1	4.03	.63	117	84.8
13. It has helped me enhance my character strengths comprehensively.	4.30	.58	60	93.8	3.91	.58	62	83.8	4.09	.61	112	88.4
14. It has enabled me to understand the importance of situational task competencies, character strength and caring disposition in successful leadership.	4.22	.55	60	93.8	4.03	.60	64	86.5	4.12	.58	124	89.9
15. It has promoted my sense of responsibility in serving the society.	4.19	.56	59	92.2	3.91	.58	60	81.1	4.04	.58	119	86.2
16. It has promoted my overall development.	4.27	.65	57	89.1	3.97	.64	62	83.8	4.11	.66	119	86.2
17. The theories, research and concepts covered in the program have enabled me to understand the characteristics of successful service leaders.	4.28	.58	60	93.8	3.97	.60	62	83.8	4.12	.60	122	88.4
18. The theories, research and concepts covered in the program have helped me synthesize the characteristics of successful service leaders.	4.22	.60	58	90.6	4.00	.53	65	87.8	4.10	.57	123	89.1

Note. ^a Scores on the scale/subscale higher than or equal to 4 were treated as positive responses. ^b For every item, respondents with positive responses (options 4-5) are shown in the Table. [†] 1=Strongly Disagree; 2=Disagree; 3=Neutral; 4=Agree; 5=Strongly Agree.

Table 6. Summary of the participants' Global Satisfaction with the program

	Satisfaction with the program ^a	Semester 1 (n = 64)				Semester 3 (n = 74)				Overall (n = 138)			
		M	SD	Positive Responses ^b		M	SD	Positive Responses ^b		M	SD	Positive Responses ^b	
				n	%			n	%			n	%
1.	Will you suggest your friends to take this program? ^c	4.11	.72	55	85.9	3.84	.78	53	71.6	3.96	.76	108	78.3
2.	Will you participate in similar programs again in the future? ^c	3.78	1.00	42	65.6	3.53	.80	37	50.0	3.64	.90	79	57.2
3.	On the whole, are you satisfied with this program? ^d	4.31	.53	62	96.9	3.90	.58	57	77.0	4.09	.59	119	86.2

Note. ^a Scores on the scale/subscale higher than or equal to 4 were treated as positive responses. ^b For every item, respondents with positive responses (options 4-5) are shown in the Table. ^c 1 = Definitely will not, 2 = Will not, 3 = Not sure, 4 = Will, 5 = Definitely will. ^d 1 = Very dissatisfied, 2 = Moderately dissatisfied, 3 = Neutral, 4 = Satisfied, 5 = Very satisfied.

The results of one-way ANOVAs showed that there were significant differences on perceptions of program content, program implementer, program benefits, total effectiveness and global satisfaction between students taking service leadership course in regular semester (Semester 1) and intensive summer term (Semester 3) respectively, with students participating in Semester 1 perceived better subjective outcomes than did those participating in intensive summer term (see Table 7). Hypotheses 2a to 2e were supported.

Table 7. One-way ANOVA comparing the evaluations on the program of participants in different semesters

Subjective Outcome Evaluation Scales	Semester 1 (n= 64)		Semester 3 (n= 74)		Comparison	
	Mean	SD	Mean	SD	F	p
Program Content	4.20	.40	3.90	.47	15.54	< .001
Program Implementer	4.48	.42	4.21	.39	15.10	< .001
Program Benefits	4.19	.45	3.88	.45	16.50	< .001
Total Effectiveness	4.27	.36	3.97	.38	21.62	< .001
Global Satisfaction	4.07	.68	3.76	.63	7.74	< .01

Table 8. Correlations coefficients among the variables

	1	2	3	4
1. Program Content	1			
2. Program Implementer	.60***	1		
3. Program Benefits	.71***	.54***	1	
4. Total Effectiveness	.87***	.76***	.93***	1
5. Global Satisfaction	.62***	.43***	.61***	.65***

Note: *** $p < .001$.

Furthermore, correlation analyses showed that all variables (PC, PI, PB, TE, GS) were all correlated with each other, with Pearson's r ranging from .43 to .93 (see table 8). Hypotheses 3a to 3j were supported. Multiple regression analyses further indicated that both program content and program implementer were significant predictors of perceived benefits of the students, with $\beta = .61$ ($p < .001$) and $.17$ ($p < .05$) respectively, explaining 53% of the total variance of perceived benefits (Table 9). Hypotheses 4a and 4b were supported. In addition, among the relationship of program content, program implementer and program benefits on global satisfaction of the students, both program content and program benefits were significant predictors of global satisfaction of the students, with $\beta = .36$ ($p < .001$) and $.34$ ($p < .001$). The predictor variables explained 44% of the total variance of global satisfaction of the participants (see table 9). Hypotheses 5a and 5c were supported.

Table 9. Multiple regression analyses predicting perceived benefits and global satisfaction

Predictors	Program Benefits				Global Satisfaction			
	B	SE	β	R^2	B	SE	β	R^2

Program Benefits					.48	.13	.34***	

Note: * $p < .05$; *** $p < .001$.

DISCUSSION

This study aimed at assessing the effectiveness of a service leadership subject in a university in Hong Kong. The findings echoed the results of previous studies [12-14], showing that the participants had positive views perceptions on course content, implementers, benefits and global satisfaction after participating in the subject. The findings reveal that the subject was able to introduce the theories and concepts of service leadership to the students and promoted their leadership competencies.

However, participants of subject offered in the regular semester (Semester 1) rated higher on the subjective outcomes in the four aspects (PC, PI, PB and GS) than did those participated in the intensive summer semester (Semester 3). As the summer semester lasted for seven weeks to cover 13 lectures, the students needed to attend two lectures each week. Thus, the students may have difficulties to fully comprehend the concepts and theories, and may exhibit pressure in preparing presentations and assignments. The tight program schedule and stresses may affect their perceptions of course arrangement, instructors, benefits and global satisfaction. As such, there is a need to refine the flow and content of the subject in order to meet the tight program schedule, and provide more support to the students on their preparation of presentations and assignments.

As predicted, course content and quality of implementers are important predictors of perceived benefits of the students. As such, it is important to develop a curriculum that can inspire students on the essential components of service leadership and enhance their competencies and character strengths in becoming a service leader. In particular, program activities and interactions among peers are essential elements for students to acquire the knowledge of service leadership. From the literature [15, 16], experiential learning involves direct experience, reflections and observation, abstract conceptualization, and active experimentation [15], which is a practical pedagogy to engage students in the leadership process, and encourage them to reflect and make meanings through their experiences and reflections [16]. Hence, it is necessary to enrich the curriculum with more experiential activities for the students to experience and reflect on their leadership style. In addition, qualities of instructors are critical in transferring knowledge and practice to university students. In education literature, essential practices of student-teacher contacts, constructive feedback to students, high expectations, and respect for diverse potentials and learning paths of students are evident to facilitate student development and learning [17]. Besides, instructors serve as role-models of a service leader for students. Their attitudes, behaviors and responses to students reflect the attributes of a service leader.

Furthermore, the findings indicated that program content and perceived benefits were predictors of students' global satisfaction, which echo the findings of previous research [12-14]. Obviously, perceived benefits are important predictors in influencing students' global satisfaction, as the strengthening of students' competencies and character strengths fulfils participants' expectations of the course, which increases their satisfaction of the course. Moreover, the program content determines the "what" and "how" of service leadership theories and concepts are conveyed to the students, which affects their global satisfaction. Interestingly, program implementer, relative to program content and perceived benefits, was not a significant predictor of students' global satisfaction. Students felt satisfied with the course only when they acquired the knowledge of service leadership, and perceived changes

of their intrapersonal and interpersonal competence. The performance of program instructors becomes secondary when compared with program content and perceived benefits. These findings are in line with previous findings [18].

There are several implications of the study. First, the findings indicated that students showed positive perceptions on course content, instructors, benefits and global satisfaction of the participants after participating in a service leadership subject. As commented by Eich [16] that “there has been little empirical research on student leadership program quality and program activities that contribute significantly to leadership development and learning” (p. 176), the present study shows empirical support on the effectiveness of a quality service leadership subject conducted in a university. Second, in the urging needs in equipping young people with 21st Century skills to face the present social and economic challenges [2], service leadership is proved to be essential in university education to enhance relevant task competencies, character strengths and a caring composition of the students [10]. Third, while program content and quality of implementer contribute to the perceived benefits of the participants, program content and perceived benefits are predictors of participants’ satisfaction of the course. The findings reaffirm Haworth and Conrad’s [19] comments on the importance of interactive teaching and learning, well-structured curriculum and participatory atmosphere among students are essential attributes of a high-quality leadership education program. Last but not the least, program schedule may contribute to the difference on program effectiveness between subject offered in regular semester and intensive summer semester. Course implementer may need to refine the structure and content of the service leadership program, and provide more flexibility and support to the students to minimize the constraints caused by tight program schedule.

Despite the very positive evaluation findings, there are two main limitations of the study. First, the study employed a subjective outcome evaluation approach to examine the effectiveness of a service leadership subject in Hong Kong. There is a need to conduct objective outcome evaluation [20] to examine the changes of students’ outcomes of task competencies, character strengths and caring attributes before and after participating in the subject. Along with this line, the findings are based on a cross-sectional data collected at the end of the semester, it is suggested to track the changes of students’ outcomes. Actually, we have conducted such studies in the past [21]. Second, qualitative studies can incorporate with subjective outcome evaluation to give a full picture of the experience and changes of the students after taking the subject. Focus group interviews, case study and reflective journals are useful qualitative methods to capture the processes of changes that the students experience [22].

Despite the limitations, this study provides empirical support on the importance of promoting service leadership education to college students in Hong Kong, and identifies key components necessary for designing and implementing a quality leadership subject. As suggested by Shek and Chung [23] that there are “unfinished tasks” of service leadership program evaluation and examination of factors leading to program success, the present study takes a humble step to the quest.

ACKNOWLEDGMENTS

The development of the Service Leadership subjects and preparation for this paper are financially supported by the Victor and William Fung Foundation and the Service Leadership Endowed Professorship in Service Leadership Education at The Hong Kong Polytechnic University. Hung Hom, Hong Kong, PR China

ABSTRACT

Universities in Hong Kong have implemented general education programmes since September 2012 when the undergraduate education was formally extended from three years to four years. At The Hong Kong Polytechnic University (PolyU), a new general education curriculum entitled ‘General University Requirements’ (GUR) has been incorporated in its four-year undergraduate education, aiming to cultivate five desired graduate attributes (critical thinking, problem solving, effective communication, ethical leadership, and lifelong learning). To investigate students’ actual learning and development over time under the new general education programme, a yearly online survey was conducted for three consecutive years ($N = 460$). Results showed that students gained significant improvements in their development of the five desired generic competences after two-year university study, despite a slight decrease in some of these attributes in the second year of their university life. These findings suggest that the new general education programme at PolyU is effective in promoting students’ personal development and its intended learning outcomes are largely achieved.

INTRODUCTION

Higher education system is undergoing changes in face of globalization and emergence of the knowledge economy. In Hong Kong, the University Grants Committee (UGC) mandated the extension of undergraduate education for one additional year (i.e., from 3-year to 4-year) in eight public universities starting from 2012/2013 academic year. The additional year allows the universities to implement their new general education (GE) programs, which aim to help students develop desirable generic attributes such as critical and higher-order thinking, effective communication, leadership, ethical reasoning, and lifelong learning [1], and thus promote students' all-round development. However, little is known about the actual impact of the GE reform on student learning and development. To address this question, the present study investigated how students change pertaining to five desirable generic attributes during their three-year study of one new GE program at The Hong Kong Polytechnic University (PolyU), one of the public universities in Hong Kong.

Educational Changes and Learning Outcomes Assessment

It is believed that higher education adds value to individual development [2]. What university graduates have achieved from university learning has long-term effects of shaping their life and determining their career development [3]. Furthermore, as contemporary economy is primarily based on knowledge and service, competitiveness of citizens is crucial to competitiveness and success of a society [4]. As such, the University Grants Committee of Hong Kong (UGC) [5] believed that Hong Kong's vision to be Asia's world city 'is only possible if it is based upon the platform of a very strong education and higher education sector'. It is this profound worth of higher education that calls for investigations on how university curriculum affects students and to use this information to increase effectiveness of higher education.

In recent years, employers and researchers criticize that what undergraduate students learned in college are falling well short of 21st Century's demands and higher education institutions may not effectively teach foundational skills that promote student success in contemporary knowledge society [6-7]. These concerns prompted a great deal of research especially in North American, Europe, and Australia and the results suggest the importance of a systematic approach to embed a wide range of generic attributes beyond disciplinary expertise or knowledge across curricula in university education [8-10]. In response, more and more higher education institutions have placed higher priority on cultivating students with more generic competences or 'soft skills', by revising teaching practice, implementing 'high-impact' educational programs or integrating General Education (GE) in university curricula. For instance, the Association of American Colleges and Universities [11] has launched a campaign to promote contemporary liberal education and proposed four learning outcomes essential for students to thrive in rapidly changing world, including 'knowledge of human cultures and the physical and natural world', 'intellectual and practical skills', 'personal and social responsibility', and 'integrative and applied learning'.

With these far-reaching educational changes comes research on assessment of actual student accomplishment as a result of university study [12-14]. Particular across the United

States, there has been a great deal of momentum behind student learning outcomes assessment. For example, according to two national surveys conducted by the National Institute for Learning Outcomes Assessment (NILOA) [15], most higher education institutions have applied various assessment approaches such as student surveys and classroom-based assessments to perform learning outcome assessment. Besides, researchers have explored the impacts of contemporary educational practice, especially liberal education on student achievement [13, 16-18]. Basically, these studies suggest that numerous teaching and learning practices (e.g., first-year seminars, reflective learning, learning communities, group project, global learning, service learning, etc.) involved in liberal education are effective to foster essential learning outcomes in college, such as critical and higher-order thinking, moral reasoning, ethical leadership, civic and social responsibility, global looking and multicultural competences.

Education Reform and Emphasis on General Education in Hong Kong

In recent decades, Hong Kong has experienced significant economic and social-cultural changes, including the historical change from a British colony to a Special Administrative Region of China, an increase in economic development and living standards, and the structural shift from a manufacturing-oriented economy to a knowledge- and service-based economy [19]. All these factors make quality higher education particularly important for developing people with a broad knowledge base and multiple competences to sustain Hong Kong's development [20]. However, the 3-year undergraduate education under the British framework in Hong Kong has long been criticized for its over-specialization and emphasis on passive learning [21]. University curricula that concentrate on specialist knowledge upon student enrollment might successfully help students develop intellectual competence, yet they were inadequate to nurture other generic attributes such as critical thinking, leadership, and communication skills. Just as pointed out by Freake [1], Hong Kong university graduates were 'technically knowledgeable upon entry to the workforce, but with limited ability to develop over time and adapt to new situations'. Similar concern was indicated by a market survey which found that over 80% of Hong Kong employers were not confident that Hong Kong students developed sufficient generic attributes such as creativity, analytical thinking, leadership and interpersonal skills [22]. The survey also revealed that approximately 90% of the employers thought that Hong Kong students performed worse than their North American counterparts.

As a result, education reform is in great need to address these concerns and respond to demands of today's society. To this end, Hong Kong Education Commission raised education reform proposals in 2000 and UGC mandated the formal structural change in higher education system in 2012/2013. Specifically, the eight public universities funded by UGC extended the length of their undergraduate education from three to four years and incorporated GE programs in the new curricula. It is expected that the new 4-year undergraduate curricula would contribute to the development of qualified graduates with holistic competences to form a solid foundation for Hong Kong's economy, development of society, and its place in the fast-changing world [23].

As UGC did not mandate a formal structure for GE in Hong Kong, each university independently developed their own GE programs [1, 21]. Despite divergence in some specific common core requirements of GE curricula in different universities, three features were commonly shared [21]. First, a set of intended learning outcomes were emphasized to cultivate desirable graduate attitudes, which focused on multidisciplinary knowledge, multi-perspective, critical thinking, communication, problem-solving, civic responsibility, ethic reasoning, leadership, lifelong learning, and global outlook [1]. Second, to align with the intended learning outcomes, traditional teacher-centered pedagogy emphasizing book learning and rote memorization was altered to a more engaging and student-centered pedagogy, such as individual project and group presentation. Third, more authentic forms of assessment were adopted accordingly to motivate student leaning and support leaning outcomes [21].

Basically, the GE curricula in Hong Kong are based on a US-style general education framework [21]. In fact, most teaching and learning practices involved in Hong Kong GE curricula were similar to that being regarded as ‘good practices’ or ‘high-impact educational practices’ in the United States [13, 24]. As mentioned earlier, these practices adopted in general education have been widely studied in USA and vetted as positively contributing to university students’ holistic development and growth [e.g., 3, 13]. However, whether they are also effective in Hong Kong remains unknown.

Compared with the long history of general education in the United States, Hong Kong GE program represents an entirely new curricular structure and educational philosophy. As a result, it may have ‘less legitimacy as a valued education undertaking and thus will be more difficult to develop as an integral component of undergraduate education’ [21]. On the other hand, Hong Kong students are used to Chinese culture and learning styles, such as didactic training, thus they may have reluctance and difficulties in adapting to the more active mode of pedagogies associated with GE subjects. Just as asked by Jaffee [21]: ‘will the students suddenly be prepared to engage, interact, debate, participate, discuss, and criticize?’. Concerning these challenges, it cannot be taken for granted that GE programs in Hong Kong are effective as they were in USA. As a result, there is a need to investigate the actual changes of students and provide evidence for the effectiveness of general education in Hong Kong.

Assessment of Student Learning Outcomes under General Education in Hong Kong

As GE programs in Hong Kong vary in structure in eight universities, assessment of students’ learning outcomes should accordingly pertain to the specific GE curriculum. Despite the importance of effective assessment of student achievement under the new GE curricula, only a few universities have carried out evaluation projects, among which most were preliminary and focused on pilot courses of new GE curricula. For example, one institution formally evaluated a general education foundation course during its pilot stage, while did not report any evaluation findings in formal implementation [25]. Another university launched a 2-year study to assess the effectiveness of pilot courses of its GE program [26], but no evaluative findings were published.

At The Hong Kong Polytechnic University (PolyU), a five-year longitudinal evaluation project involving multiple evaluation strategies to systematically investigate the effectiveness

of its new GE program has been implemented since 2012/13 academic year [27]. At PolyU, the new GE curriculum entitled 'General University Requirements' (GUR) includes six core components: Freshman Seminar, Language and Communication Requirements, Leadership and Intrapersonal Development, Cluster Area Requirements, Service Learning and Healthy Lifestyle. These GUR components cover a wide range of subjects and intended learning outcomes, which are aligned with five desired graduate attributes defined by PolyU: problem solving, critical thinking, lifelong learning, ethical leadership, and effective communication [28]. Despite the challenges in implementing GE in Hong Kong we mentioned before, the GUR subjects were overall well-received by both students and teaching staff [27, 29-31]. Evaluation findings on one specific subject developed to satisfy the Leadership and Intrapersonal Development requirement also showed that students were not only satisfied with the course [32, 33], but also demonstrated positive changes after taking the course [34].

While the abovementioned findings could support effective implementation of the GUR at PolyU, it is still not clear whether students had significant personal development not just in a single course. To answer this question, the current study sought to assess students' learning and development during GUR study by comparing their ratings on five desired graduate attributes of PolyU across three years. This longitudinal objective outcome evaluation would provide more convincing evidence on students' changes and personal growth over time [35].

OUR STUDY

Participants of the longitudinal study are PolyU undergraduate students under the 4-year curriculum enrolled in 2012-2013 academic year when the GUR was first implemented. Students are invited to complete an online survey every year and their informed consent are obtained before the first wave of data collection. Up to 2014-2015 academic year, three waves of data have been collected.

In the first wave of data collection, a pool including 1,000 students from eight faculties/schools at PolyU was initially selected based on a stratified random sampling method. These 1,000 students were invited through emails and/or phone calls to complete the online survey in November 2012 (i.e., 2012-2013 academic year), and 687 of them responded to the invitation while 543 completed the survey, resulting in a response rate of 54.30%. The second wave of data collection was conducted in November 2013 (i.e., 2013-2014 academic year). Those 687 students who responded to the invitation in first wave were invited again and 643 students completed the survey, resulting in a response rate of 93.59%. In the third wave of data collection conducted in November 2014 (i.e., 2014-2015 academic year), an invitation was sent to 643 students who participated in the second wave of online survey. A total of 566 students completed the online survey in the third wave, indicating a response rate of 88.02%.

In order to investigate longitudinal development of students across three years, data collected in the three waves were matched which resulted in 460 students ($M_{age} = 20.12$, $SD_{age} = .54$) who completed all three waves of online survey. Among these participants, 182 (39.57%) were male, and 278 (60.43%) were female. A total of 333 (72.39%) participants were born in Hong Kong, 113 (24.57%) were born in mainland China, and the remaining 14 (3.04%) were born in other places. Most participants reported that their parental marital status

was first marriage (82.83%). Preliminary analyses showed that there were no significant differences in measures of demographic information including age, gender composition, place of birth and parental marriage status between the matched sample ($N = 460$) and those students who dropped out of the survey after the first wave of data collection ($N = 83$).

Instruments

To measure student development regarding the five desired graduate attributes defined by PolyU, three core instruments were used: a) Chinese Interpersonal Reactivity Index (C-IRI), b) Chinese Positive Youth Development Scale (CPYDS), and c) National Survey of Student Engagement (NESS) which has been updated in 2013. A total of 13 subscales of these instruments were adopted as indicators of the five desired attributes. The alignment of each subscale with corresponding attribute to be measured is shown in Table 1 and Cronbach's alpha for each subscale in each wave is shown in Table 2.

Table 1. Alignments between subscales and desired graduate attributes at PolyU

Desired attributes	Instruments	Indicators
Problem Solving	CPYDS	Problem Solving
Critical Thinking	CPYDS	Critical Thinking
Lifelong Learning	CPYDS NSSE	Life-long Learning Higher Order Learning Reflective and Integrative Learning Learning Strategies Quantitative Reasoning
Ethical Leadership	C-IRI CPYDS	Empathy Ethical Leadership Self-leadership
Effective Communication	CPYDS NSSE	Social Competence Collaborative Learning Discussions with Diverse Others

Note. CPYDS: Chinese Positive Youth Development Scale. C-IRI: Chinese-Interpersonal Reactivity Index. NSSE: National Survey of Student Engagement.

Table 2. Reliabilities of each instrument used in three waves

Instruments	Subscales	# of items	Reliability					
			2012-2013		2013-2014		2014-2015	
			α	mean inter-item correlation	α	mean inter-item correlation	α	mean inter-item correlation
C-IRI	Empathy	11	.72	.19	.69	.17	.71	.19

	Reflective and Integrative Learning	7	.82	.40	.84	.43	.88	.51
	Learning Strategies	3	.70	.43	.75	.50	.78	.54
	Quantitative Reasoning	3	.71	.45	.70	.43	.79	.56
	Collaborative Learning	4	.70	.37	.75	.42	.76	.44
	Discussions with Diverse Others	4	.66	.33	.62	.29	.69	.36

Note. CPYDS: Chinese Positive Youth Development Scale. C-IRI: Chinese-Interpersonal Reactivity Index. NSSE: National Survey of Student Engagement.

Chinese-Interpersonal Reactivity Index (C-IRI)

Since ethical reasoning and empathy are important competences of an ethical leader [36], the present study used the Empathy (EM, 11 items) subscale of the C-IRI that adapted by Siu and Shek [37] as one measure of ethical leadership. Using a 4-point Likert scale, average score across 11 items was computed as one indicator of ethical leadership. The C-IRI has been widely used and demonstrated good reliability in previous studies [e.g., 38, 39]. In the present study, Cronbach's alpha coefficients of the EM subscale in three waves ranged from .68 to .72, indicating good reliability.

Chinese Positive Youth Development Scale (CPYDS)

The Chinese Positive Youth Development Scale (CPYDS) was developed by Shek, Siu, and Lee [40] to measure Chinese adolescents' positive youth development (PYD) attributes. The original scale contains 90 items related to 15 constructs of PYD, and has been found to be valid and reliable as a global measure of PYD in Chinese adolescents in previous studies [34, 41]. In the present study, 6 subscales of the CPYDS including Problem Solving (PS), Social Competence (SC), Critical Thinking (CT), Ethical Leadership (EL), Self-leadership (SL), and Life-long Learning (LL) were adopted to measure student developmental qualities. Using 6-point Likert scale, average scores across items in each subscale were used to form indexes reflecting students' performance in the desired graduate attributes. In the present study, the internal consistencies of the subscales were from acceptable to good as reflected by the medium to large Cronbach's alpha coefficients across three waves.

National Survey of Student Engagement (NSSE)

Another instrument used in the present study was a locally adapted version of the (NSSE which assesses student engagement in high levels of learning and development. The NSSE has been widely used at universities in many countries, including USA, Canada, Australia, and China [42-44]. The NSSE consists of 47 items pertaining to 10 Engagement Indicators (EIs) [45], including Higher-Order Learning (HO), Reflective & Integrative Learning (RI), Learning Strategies (LS), Quantitative Reasoning (QR), Collaborative Learning (CL), Discussions with Diverse Others (DD), Student- Faculty Interaction (SF), Effective Teaching Practices (ET), Quality of Interactions (QI), and Supportive Environment (SE). The present study used 6 EIs (i.e., HO, RI, LS, QR, CL, and DD) to indicate student competence in lifelong learning and effective communication (see Table 1). We adopted a 4-point Likert scale for all items in 6 subscales and calculated average scores in each subscale. In the present study, the Cronbach's alpha coefficients for these subscales ranged from .62 to .88 across three waves, suggesting good internal consistencies of adapted subscales.

FINDINGS

To explore student development over three years, 13 repeated measures analysis of variance (ANOVA) with Bonferroni post hoc tests were performed, each using one indicator of the five desired attributes at PolyU as the dependent variable. The independent variable was time, operationalized as the academic year when the data were collected and extracted (i.e., 2012-2013, 2013-2014 and 2014-2015). Results of ANOVA are summarized in Table 3.

Table 3. Comparisons of students' performance in three waves (N = 460)

Desired Attributes	Indicators	2012-2013		2013-2014		2014-2015		Repeated Measures ANOVA	
		<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>F</i>	η^2_p

	Collaborative Learning ^a	2.43	.54	2.39	.53	2.59	.54	26.27***	.05
	Discussions with Diverse Others ^a	2.27	.54	2.24	.51	2.46	.60	34.67***	.07

Note..^a Post hoc Bonferroni test indicated that rating in Wave 3 was significantly higher than rating in both Wave 1 and Wave 2. ^b Post hoc Bonferroni test indicated that rating in Wave 3 was significantly higher than rating in Wave 2. ^c Post hoc Bonferroni test indicated that rating in Wave 2 was significantly lower than rating in Wave 1. ^d Post hoc Bonferroni test indicated that rating in Wave 2 was significantly higher than rating in Wave 1.

* $p < .05$, ** $p < .01$, *** $p < .001$.

Problem Solving

Students' ability in problem solving was assessed by the CPYDS Problem Solving (PS) subscale. Results of repeated measures ANOVA showed that there were significant differences in participants' scores of PS across three academic years ($F(2, 918) = 28.80$, $p < .001$, $\eta^2_p = .06$). Bonferroni post hoc tests further revealed that the rating in 2014-2015 ($M = 4.47$, $SD = .64$) was significantly higher than the ratings in 2012-2013 ($M = 4.28$, $SD = .70$, $p < .001$) and 2013-2014 ($M = 4.24$, $SD = .66$, $p < .001$). These results suggested that participants had significant growth in their problem solving competence after two years of GUR study.

Critical Thinking

Students' critical thinking was measured by the CPYDS Critical Thinking (CT) subscale. Significant differences in participants' scores of CT across three years were also observed ($F(2, 918) = 3.95, p = .02, \eta^2_p = .02$). Participants had higher CT scores in 2014-2015 ($M = 4.67, SD = .69$) than in 2013-2014 ($M = 4.59, SD = .67, p = .02$). The results provided evidence for positive development in students' critical thinking from their second year to third year of university study.

Lifelong Learning

Students' capacity of lifelong learning was measured by five indicators: Life-long Learning (LL) subscale of CPYDS, and four subscales of NSSE including Higher-Order Learning (HO), Reflective and Integrative Learning (RI), Learning Strategies (LS), and Quantitative Reasoning (QR). While no significant differences were observed in ratings of LL among three waves ($F(2, 918) = 1.83, p = .16, \eta^2_p = .004$), significant differences were found in ratings of HO ($F(2, 918) = 65.46, p < .001, \eta^2_p = .13$), RI ($F(2, 918) = 120.63, p < .001, \eta^2_p = .21$), LS ($F(2, 918) = 11.27, p < .001, \eta^2_p = .02$), and QR ($F(1.97, 905.99) = 56.54, p < .001, \eta^2_p = .11$). For these four indicators, post hoc tests further revealed that student scores in 2014-2015 were significantly higher than their scores in both 2012-2013 and 2013-2014. Besides, for HO and QR, scores in 2013-2014 were also significantly higher than that in 2012-2013. Means and standard deviations for the four indicators are listed in Table 3. These findings suggested that students' competence of lifelong learning has been significantly improved in the third year of their university study.

Ethical Leadership

Three indicators were used to measure ethical leadership: Empathy (EM) subscale of C-IRI, the Ethical Leadership (EL) and Self-leadership (SL) subscales of CPYDS. Results of repeated measures ANOVA indicated that student scores in these three subscales had significant differences in three academic years (see Table 3). Post hoc analyses further indicated that EM score in 2013-2014 ($M = 2.88, SD = .36$) was significantly lower than that in 2012-2013 ($M = 2.94, SD = .37, p = .002$). For EL, the score in the second year ($M = 4.57, SD = .53$) was significantly lower than that in the first year ($M = 4.67, SD = .45, p < .001$) while marginally lower than that in the third year ($M = 4.63, SD = .49, p = .05$). Moreover, student SL score in 2014-2015 ($M = 3.86, SD = .57$) was significantly higher than that in 2013-2014 ($M = 3.79, SD = .56, p = .03$). These findings suggested that students tended to give lower ratings for their empathy and ethical leadership in their second year. Nevertheless, the ratings rebounded in third year of university study.

Effective Communication

Three subscales were adopted to assess students' effective communication including Social Competence (SC) subscale of CPYDS, Collaborative Learning (CL) subscale and Discussions with Diverse Others (DD) subscale of NSSE. Repeated measures ANOVA showed that there was no significant difference in students' scores on SC among three waves ($F(2, 918) = .31, p = .73$). However, students scored higher on CL ($F(1.97, 905.62) = 26.27, p < .001, \eta^2_p = .05$) and DD ($F(1.96, 900.05) = 34.67, p < .001, \eta^2_p = .07$) in 2014-2015 as compared to 2012-2013 and 2013-2014. In other words, in the third year of university study, students had more collaborative learning and were more likely to discuss with diverse others in their study.

DISCUSSION

In Hong Kong, GE curricula usually have two sets of intended learning outcomes [46]. One is 'program intended learning outcomes' which incorporate goals of all general education subjects, such as five desired graduate attributes of PolyU, and the other is 'course intended learning outcomes' which are more specific and should support 'program intended learning outcomes'. The rationale behind two-level design is that it is impossible to achieve all program-level outcomes through one single GE course [47]. Such a framework used in designing intended learning outcomes requires two-level assessment accordingly: course-level and program-level [47-48]. While course-level assessment of student learning outcomes have been carried out in each GE course in all universities in Hong Kong [21], including PolyU [32-34, 49], program-level assessment showing how the students learn and develop as a result of the whole general education curriculum is scanty. In this case, the present study represents a pioneering work in conducting program-level assessment in Hong Kong to reveal how well the students achieve the intended learning outcomes on program-level. Such an attempt would benefit universities and program designers in terms of continuously improving the quality of general education curricula and the whole higher education system [47, 50].

Specifically, the present study investigated learning outcomes of students enrolled in a new general education (GE) curriculum, i.e., the General University Requirements (GUR) at Hong Kong Polytechnic University (PolyU). Based on comparisons of student self-reported ratings on indicators of five desirable generic competences across three academic years, results suggest that students showed significant improvement in most developmental indicators after two-year university study. These findings strongly support previous findings that the implementation of the GUR at PolyU was successful and effective [27, 29]. Furthermore, on top of the positive findings based on subjective outcome evaluations reported in previous studies [e.g., 30, 31], students' actual development and personal growth as measured by the current objective outcome evaluation provide much stronger evidence for the accountability and value of the GUR incorporated in the 4-year undergraduate curriculum.

Regarding students' scores on indicators of the desirable graduate attributes across three years, it seems that most developmental indicators followed a U-shaped trajectory over the period. This distribution features a visible dip on the ratings during the second year of the 4-year curriculum. For example, students tended perceive themselves as having lower level of

capacity in critical thinking, life-long learning, reflective and integrative leaning, empathy, and ethical leadership in the second year (i.e., 2013-2014 academic year) than in the first year, although the tendency was significant in only two indicators (i.e., empathy and ethical leadership). It is possible that such a trend was a result of setbacks encountered in students' first year university life, such as difficulties in adjusting to new educational demands, social environments, and life styles. This reasoning is in line with great challenges revealed in research on university transition in first year [e.g., 51]. These challenges could continue to exist in sophomore year, resulting in identity confusion, low self-evaluation due to academic stress, and other social pressures, which may cause a decline in learning outcomes among sophomores [52].

Nevertheless, ratings on developmental indicators rebounded at the third year. It might be possible that students have already well adapted to university life after two years. For example, students may have developed sufficient skills and supporting networks to deal with academic and other types of stress in the third year of university life, as suggested by students' highest scores in collaborative leaning and higher order leaning strategies in the academic year of 2014-2015. It is noteworthy that students had obtained significant improvement in different aspects of generic competences after two years of university study. The improved areas included problem solving, critical thinking, higher order learning, reflective and integrative learning, learning strategies, quantitative reasoning, self-leadership, collaborative learning, and discussions with diverse other, which cover all five desired graduate attributes of PolyU. Previous research has demonstrated that good practices in general education help students develop desirable generic capacities in Western cultures [e.g., 13, 53]. Findings of the present study indicate that a US-style general education curriculum is also effective in facilitating student development in a holistic manner in Chinese culture.

Taken together, while the present finding suggests that the unique characters of GE program at PolyU help promote student generic competences, for example, more engaging pedagogies are more effective in facilitating student learning than teacher-centered lecturing method [e.g., 54], it should be noted that such a positive effect might be hindered during the first year of students' university life. In other words, students may have difficulties in accepting such a totally new teaching and learning method at the very beginning of their university life. This is consistent with some scholars' concerns that interactive pedagogies might not be readily well received by Chinese students who are largely influenced by cultural traditions [21]. As a result, universities and faculties need to develop more effective approaches to incorporate interactive teaching and learning strategies in GE curricula that take into account Chinese students' characteristics. For example, nurturing student critical thinking through writing assignment may be more easily accepted by Chinese students than asking them to make critical comments in front of all students in the class. Furthermore, more assessment studies should be conducted to reveal strengths and weakness of such approaches in Chinese contexts and use the results to improve the quality of teaching and learning. Besides, additional projects or programs aiming to help freshmen adapt to university life and requirements would help students benefit from general education curricula.

The present study also provides evidence for the effectiveness of using longitudinal self-reported data to assess student learning and personal development during university study. To carry out effective program-level assessment of learning outcomes, balancing efficiency, accuracy and cost in measuring student outcomes is a great challenge. Asking students to report how much they have achieved during a certain period is an inexpensive and efficient

method while students may not always be able to accurately judge their own growth [55]. In contrast, longitudinal assessments of objective outcomes would be more accurate in revealing student achievement during the period. In longitudinal design, objective outcomes can be measured either with actual tests (e.g., some tasks measuring critical thinking) or self-reported questionnaire. Given that the former method should require great financial and human resources (e.g., more standardized and controlled measuring environment), and students are reasonably accurate in estimating their current attributes or skills [55], combining longitudinal design and self-reported measures represents a cost-effective and relatively accurate method to examine student personal development.

Several limitations of the present study should be noted. First, the study only measured student outcomes in three time points and used analysis of variance (ANOVA) to examine changes, which despite of its merits cannot reveal systematic change rates across different waves over time [56]. As a result, future research should follow up student development for a longer time period and using more powerful statistical techniques such as growth curve modeling to identify the developmental trajectory of students [56]. Second, the present study examined student development in one university in Hong Kong. Therefore, the relative advantages and disadvantages of the GUR as compared to other GE curricula in other high education institutions were unknown. Future assessments could conduct comparisons on student learning outcomes across different universities in Hong Kong and abroad (e.g., universities in mainland China). Third, the present study is quantitative research in nature, which is not able to provide students' in-depth perceptions on their experience (i.e., qualitative data) during university study to help researchers interpret and reflect on the findings. To gain a more comprehensive understanding of student learning outcomes and to triangulate the current findings, multiple research methods including qualitative studies should be used in future assessment of student learning outcomes.

Fourth, as no control group was used in this study, it is possible that the change is simply a result of developmental maturation. While it is a logical possibility, it is noteworthy that there is no research suggesting that university students necessarily show a rise in developmental indicators in this study [e.g., 3, 57].

Finally, while we interpret the present findings in terms of the beneficial effect of the GUR at PolyU, the changes may also be due to the beneficial effect of the overall four-year programme (i.e., including the effects of Major Programme). Since both the GUR and the discipline-specific program are offered at the same time, it is difficult, if not impossible, to separate their specific effects. However, two points should be noted when we interpret the findings. Primarily, evaluation of specific GUR subjects, such as leadership subjects, shows their contribution to the development of desired graduate attributes of PolyU students. Besides, as GUR subjects concentrate more in the first two years of the 4-year undergraduate program, it is more likely that the beneficial effect is a result of students' GUR study.

Chapter 331

**PROMOTION OF SERVICE LEADERSHIP QUALITIES
IN CHINESE UNIVERSITY STUDENTS:
OBJECTIVE OUTCOME EVALUATION BASED
ON SIX WAVES OF DATA**

ABSTRACT

Economies worldwide are shifting from manufacturing to service economies, resulting in a demand for new leadership qualities. The Hong Kong Institute of Service Leadership & Management (HKI-SLAM) proposed the Service Leadership and Management Model which highlights the importance of leadership competencies, moral character, and caring dispositions as crucial leadership attributes in service economies. The Global Youth Leadership Programme (GYLP) was developed for students from The Hong Kong Polytechnic University and the Peking University, aiming at nurturing students' service leadership qualities. The present paper reports findings based on objective outcome evaluation utilizing six waves of data. Results showed that students had significant improvement over time on different outcome measures, including positive youth development attributes, service leadership competencies, and life satisfaction. The study provides evidence for the effectiveness of service leadership education and GYLP. Implications for nurturing service leaders and promotion of holistic development of students through leadership programmes are discussed.

INTRODUCTION

One of the most challenging and imperative objectives of tertiary education is to help students develop integrity and strength of character which prepare them for leadership [1]. As future professionals, students should acquire qualities such as, “increased sensitivity and action, responsibility... directness and honesty, and high demands on themselves and others” [2]. Similarly, the Council for the Advancement of Standards in Higher Education asserted that “regardless of differences in academic discipline, organizational affiliation, cultural background, or geographical location, students must be better prepared to serve as citizen leaders in a global community” [3]. Hence, one common expectation is to nurture university students to be leaders. In a recent review of leadership theories over the past two decades, Meuser and colleagues [4] identified 49 leadership approaches/theories. Some of the more popular theories/approaches included transformational leadership, charismatic leadership, participative/shared leadership, and the trait approach to leadership.

Obviously, we have to ask whether existing leadership theories are deemed as effective and relevant in today’s time and age. Satterwhite et al. [5] observed that our understanding of leadership has evolved in the past century as the challenges we face as a global community “have increased in complexity, size, scope, consequence. As a result of this contextual evolution, our definition of effective leadership is evolving as well” [5]. This observation is concurred by Chung [6] in his latest article in the *South China Morning Post* where he spoke of the “economic complexity and challenges we face today”. He argued that “the ones who will succeed in the next 30 years will be those who recognize that the economic growth of the past will not be replicated in the same way again” (para 13). This implies two things: 1) that global economies have changed over the years; and 2) that successful leaders are those who recognize these changes, and are equipped with the skillset that meets the needs of today’s economy.

Indeed, economies worldwide are shifting from manufacturing to service economies. Service sectors are becoming increasingly contributive to nations’ Gross Domestic Product (GDP). In 2014, the service constituted 79.7% in the US, 78.3% in the UK, 71.4% in Japan, 74.7% in Singapore, and 92.7% in Hong Kong [7]. This economic shift poses new demands on the workforce, especially for that of desired leadership qualities. According to Shek and colleagues [8], while traditional manufacturing economies require leaders to be equipped with professional, hands-on knowledge, and skills, leaders are expected to be more “people-oriented” and demonstrate “soft skills” beyond hard skills in service economies. Individuals respect and prefer service leaders who are moral, caring, and willing to serve with empathy and integrity, rather than merely exerting power to exercise manipulation.

Against this background, The Hong Kong Institute of Service Leadership and Management (HKI-SLAM) under the leadership of Dr. Po Chung (co-founder of DHL International, Asia Pacific and Chairman Emeritus of DHL Express (Hong Kong) Ltd.) proposed the Service Leadership and Management Model which highlights the importance of leadership competencies, moral character, and caring dispositions as crucial leadership attributes in contemporary service driven society. According to the model, having leadership competence alone is not enough; moral character and caring dispositions are also vital to successful leadership. Chung [9] further proposed a holistic model which delineated 12 dimensions of an effective service leader. The dimensions are organized into four categories:

Doing (e.g., possessing functional expertise, being physically healthy); *Thinking* (e.g., having emotional and cognitive competencies); *Growing* (i.e., being able to establish and maintain positive relationships with followers, and adopting the attitude of life-long learning); and *Being* (e.g., exercising compassion, morality, and spirituality).

In order to nurture students to become leaders, leadership programmes in tertiary education settings have proliferated since the eve of the 21st century. Binard and Brungardt [10] reported that there were over 600 campuses in the United States providing leadership training. In response to the longstanding question of whether leadership can be “taught”, the authors investigated the impact of leadership programmes on various student outcomes. Findings revealed that students who participated in leadership programmes had improved in leadership behaviours (e.g., inspiring a shared vision, enabling others to act, modelling, encouraging others, and challenging the process), as compared with their counterparts who had never attended such collegiate leadership training.

Although collegiate leadership training has existed for a while, formal leadership programmes are still relatively new. It may be due to two main reasons. First, there is yet to be a consensus on a particular theory or approach about *how* to develop leaders [11]. Second, the differentiation between “leader development” vs. “leadership development” remains clouded. Leader development activities target specifically on nurturing skills and traits of individuals “designated” as a leader or an emerging leader. This notion is somewhat in line with the elitist approach of leadership. In contrast, leadership development refers to nurturing intrapersonal, as well as leader traits and skills that would enable effective interpersonal interactions and facilitate leader-follower exchange [12].

Day et al. [13] pointed out that “leaders do not ‘develop’ in workshops or seminars but rather ‘in the so-called white space between such leader development events’ (p. 80). This “white space” may be certain trigger events that enable individuals to experience and construct a personally meaningful narrative about their own leadership [14]. In line with the above perspectives, the Global Youth Leadership Programme (GYLP) was developed for students from The Hong Kong Polytechnic University and the Peking University, aiming at nurturing students’ service leadership qualities, including leadership competencies, moral competencies, and caring disposition. The GYLP was designed such that students first attended a series of lectures where the concept of service leadership and psychological theoretical underpinnings were introduced. Existing leadership theories were also presented and students were guided to evaluate and compare and contrast different leadership theories while reflecting on the importance and relevance of the service leadership model in the present service economy. During the lectures, students were also given the opportunity to engage in personal reflection on their service leadership competencies (i.e., moral character, leadership competencies, and caring dispositions) and how they can apply these competencies in serving others.

Upon completion of the service leadership lectures, students were given the chance to gain hands-on experience and apply service leadership concepts, and reflect on their competencies through a wide-range of talks, presentations, experiential activities, and service in mainland China, Hong Kong, and Cambodia. For instance, during their initial trip to Beijing and Xi’an, students attended different talks regarding contemporary issues in China such as Chinese Foreign Policy, China’s Five-Year Plan, and Minority Tribes in Western China. Students also engaged in dialogues with renowned community leaders and executives of large corporations.

Students took the self-initiative to conduct research in preparation of presentations during the “Youth Forum on Poverty in Hong Kong and Chinese Mainland” in Hong Kong. Students prepared presentations on the causes and government policies regarding poverty, and looked into what the young generation can do to alleviate poverty. They also engaged in an experiential activity of role-playing as a homeless, sleeping in the streets, and scavenging cardboard boxes to make money to buy food. Students generally reflected that they had positive experience about the programme, such as

“Observing something bad happening around us urges me to think more about how to change the situation. And I felt a greater eagerness to take some actions” and “Leadership should be at the base of the spirit of service, so that one can become a valuable and admirable leader. Though I am still a university student, I will try my best to prepare for the future in my position and serve the society”.

Table 1. Detailed GYLP activities

Beijing and Xi'an Trip
• Opening ceremony • Welcome lunch • Service leadership lecture • Talk: Foreign Policy of China • Visit: Migrant worker community service center • Visit: Organic farm • Visit: African culture project • Visit: Tencent office • Leaders Dialogue Forum • Visit: United Nation Development Programme • Visit: Hong Kong Special Administrative Region Beijing Office • Talk: 125 National Planning • Visit: Museum of Qin Terracotta Warriors and Horses • Talk: Development policy of Western China • Talk: Chinese culture and society • Visit: Deprived village of Shanxi • Talk: Minority tribes in Western China • Visit: Community walk in Muslim district • Group presentation • Visit: Great Wall of China
Hong Kong Trip
• Talk: Social welfare system in Hong Kong • Visit: New Life Psychiatric Organization • Visit: Hong Kong Christian Service Ethnic Minority Services • Practical Dreamers seminar • Talk: Environmental challenges of Hong Kong and Mainland in Global context • Visit: Legislative council • Experiential activity: Role-playing as homeless • Youth Forum on Poverty in Mainland China and Hong Kong • Youth Forum dinner
Cambodia Trip
• Preparation and conducting rural asset survey • Visit: Slum area • Cultural programme at learning village • Talk: Social issues in Cambodia • Orientation with local volunteers • Service at local primary school and orphanage • Visit: Village area • Visit: Killing Fields Museum of Cambodia

Finally, during the Cambodia trip, students provided service to the needy. For instance, some students visited a village where farmers experienced the problem of drought and devised creative ways of irrigation to alleviate the problem. Another group of students visited a primary school where they organized vision screening projects and helped raise awareness of ocular health among the underprivileged in the area. A third group of students served in an orphanage housing children diagnosed with AIDS. The GYLP service leaders developed creative activities such as photography to allow the students to capture and express things in life that they felt grateful towards. Through different services, students demonstrated their service leadership competencies to understand the needs of different parties and applied leadership competencies, care, and moral character, alongside their discipline knowledge to propose solutions to the problems faced by the underprivileged. The detailed programme can be seen in Table 1.

In order to gain a better understanding of the effectiveness of the programme, objective evaluation outcome evaluation data were collected from students at six waves of data during different stages of the Programme. The present paper reports the findings arising from the evaluation study.

OUR STUDY

A total of forty-eight university students (37 females; Mage = 19.65 years, SD = 0.76) participated in the GYLP, in which 24 students were from The Hong Kong Polytechnic University and the other 24 students were from Peking University. The students were enrolled into the programme via application and interview. Besides students from Hong Kong and mainland China ($n = 42$, 87.5%), there were three Koreans (6.25%), one Taiwanese (2.08%), one Thai (2.08%), and one American (2.08%) joining the programme. The numbers of students participated in different trips varied because some students skipped one or two trips and some quitted the programme halfway due to other commitment (see Table 2). Finally, a total of 39 students completed all the assessments.

Table 2. Description of trips of GYLP

Trip	Time	Assessment time	No. of students
Mainland China trip	July 7-27, 2013	Pretest: July 8, 2013	47
		2 nd test: July 12, 2013	48
		3 rd test: July 25, 2013	47
Hong Kong trip	January 13-19, 2014	4 th test: January 19, 2014	44
Cambodia trip	July 27 - August 6, 2014	5 th test: July 24, 2014	41
		6 th test: August 5, 2014	40

Note: same subscript letter indicates no significant difference in mean level.

Instrument

The students were invited to respond to an identical objective outcome evaluation form at six time points, including baseline test before the service leadership class, posttest of service leadership class (i.e., 2nd test), posttest of mainland China trip (i.e., 3rd test), posttest of Hong Kong trip (i.e., 4th), pretest of Cambodian trip (i.e., 5th test), and posttest of Cambodian trip (i.e., 6th test). Due to the short duration, there was no pretest for the Hong Kong trip. This evaluation form includes ten positive youth development attributes, life satisfaction and service leadership qualities and beliefs. It has been repeatedly used in the evaluation of the subject “Service Leadership” with good psychometric properties [15, 16]. Students completed the form in a self-administration manner. The internal consistencies of the scales used in this study were generally good (see Table 3).

Positive Youth Development

The items of positive youth development were selected from the Chinese Positive Youth Development Scale (CPYDS; 17) with modification to fit the context of the programme (31 items). These items assess social competence, cognitive competence, emotional competence, moral competence, behavioral competence, clear and positive identity, belief in the future, self-determination, spirituality, and resilience. According to Shek and Ma [18]’s factor analysis, there are four higher-order factors, including cognitive-behavioral competencies, positive identity, prosocial attributes, general positive youth development qualities. In this study, we tested students’ changes of positive youth development on three higher order factors (i.e., cognitive-behavioral competencies, positive identity, and general positive youth development qualities) and positive youth development total score. Cognitive-behavioral competencies score includes the subscales of cognitive competence, behavioral competence and self-determination; positive identity score includes subscales of clear and positive identity as well as belief in future; general positive youth development qualities score includes the subscales of emotional competence, social competence, moral competence, resilience, and spirituality; positive youth development total score includes all of the subscales of positive youth development attributes. With negative items reverse coded, a higher score denotes a higher level of positive youth development.

Life Satisfaction

Students reported their overall satisfaction with life via the five-item Satisfaction with Life Scale (SWLS) developed by Diener and associates [19]. This scale has been repeatedly used in Chinese population [20]. Mean scores were taken with higher scores indicating higher levels of life satisfaction.

Service Leadership Qualities and Beliefs

Students reported their service leadership qualities and beliefs via a scale developed based on the service leadership model [16, 21]. The scale assesses critical components of service leadership, including self-leadership, caring disposition and character strengths as well as service leadership beliefs. Mean scores were taken with higher scores indicating higher levels of service leadership qualities and stronger endorsement of service leadership beliefs.

FINDINGS

Series of ANOVA analyses with time as repeated measure were conducted on the outcome variables. Time effect was significant on all outcome measures, which indicated that positive youth development, life satisfaction and service leadership qualities and beliefs changed positively during the programme participation. LSD post-hoc analyses were then used to understand the variation across different time points. We focused on the comparison between the baseline test and the subsequent tests, and that between the pretest and the posttest of one trip. The results were presented in table 3.

First, three components of positive youth development all changed positively over time (cognitive-behavioral competence: $F(5,31) = 5.57, p < .001, \eta^2_p = .47$; positive identity: $F(5,31) = 7.12, p < .001, \eta^2_p = .51$; general positive youth development qualities: $F(5,34) = 10.82, p < .001, \eta^2_p = .61$). For cognitive-behavioral competence, compared with the baseline test, the scores of all subsequent tests were higher (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .001$; 1st vs. 4th: $p < .001$; 1st vs. 5th: $p < .01$; 1st vs. 6th: $p < .001$). The score increased from the baseline test to the second test, maintained stable between the second test and the fifth test, and finally increased again from fifth test to the sixth test ($p < .05$). Similar pattern was observed in positive identity. Compared with the baseline test, the scores of all subsequent tests were higher (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .01$; 1st vs. 4th: $p < .001$; 1st vs. 5th: $p < .01$; 1st vs. 6th: $p < .001$). The score increased from the baseline test to the second test, maintained stable between the second test and the fifth test, and finally increased again from fifth test to the sixth test ($p < .01$). For general positive youth development qualities, compared with the baseline test, the scores of all subsequent tests were higher (1st vs. 2nd: $p < .001$; 1st vs. 3rd: $p < .001$; 1st vs. 4th: $p < .001$; 1st vs. 5th: $p < .01$; 1st vs. 6th: $p < .001$). The score kept increasing from the baseline test to the third test (2nd vs. 3rd: $p < .05$), but declined from the third test to the fourth test ($p < .05$). With no difference between the fourth test and the fifth test, the score increased from the fifth test to the sixth test ($p < .001$). Taking all positive youth development attributes as a whole, we found the time change as well ($F(5,34) = 10.72, p < .001, \eta^2_p = .61$). Compared with the baseline test, the scores of all the subsequent tests were higher (1st vs. 2nd: $p < .001$; 1st vs. 3rd: $p < .001$; 1st vs. 4th: $p < .001$; 1st vs. 5th: $p < .01$; 1st vs. 6th: $p < .001$). The total score increased from the baseline test to the second test, maintained stable from the second test to the fifth test, and finally increased again from the fifth test to the sixth test ($p < .01$). All these findings suggested that the programme was effective to promote positive youth development of students. As we found a decline in general positive youth development qualities from the third test to the fourth test, more effort is needed to maintain the programme benefits.

Second, time change occurred in life satisfaction ($F(5,34) = 11.60, p < .001, \eta^2_p = .63$). LSD post hoc analysis revealed that the score of baseline test was lower than all of the subsequent tests ($ps < .001$). In addition, there was no change from the second test to the fifth test, but with an increase from the fifth test to the sixth test ($p < .01$). Students' life satisfaction reached the highest point at the sixth test (6th vs. 4th: $p < .001$; 6th vs. 3rd: $p < .01$; 6th vs. 2nd: $p < .01$). These results suggested the programme was effective to boost students' life satisfaction.

Third, time changes occurred in service leadership qualities (self-leadership: $F(5,34) = 12.84, p < .001, \eta^2_p = .65$; caring disposition: $F(5,34) = 4.55, p < .01, \eta^2_p = .40$; moral

character: $F(5,34) = 14.44$, $p < .001$, $\eta^2_p = .68$) and service leadership beliefs ($F(5,34) = 3.29$, $p < .05$, $\eta^2_p = .33$). For self-leadership, compared with the baseline test, the scores of all subsequent tests were higher (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .01$; 1st vs. 4th: $p < .01$; 1st vs. 5th: $p < .05$; 1st vs. 6th: $p < .001$). Specifically, the score increased from the baseline test to the second test ($p < .001$), maintained stable between the second test and the fifth test, and finally increased again from the fifth test to the sixth test ($p < .05$). Similar pattern was found in caring disposition, in which the score of baseline test was lower than the subsequent tests (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .01$; 1st vs. 4th: $p < .01$; 1st vs. 5th: $p < .05$; 1st vs. 6th: $p < .001$). Specifically, the score increased from the baseline test to the second test ($p < .01$), maintained stable between the second test and the fifth test, and finally increased again from fifth test to the sixth test ($p < .05$). Similarly, for moral character, the score of baseline test was lower than the subsequent tests (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .001$; 1st vs. 4th: $p < .001$; 1st vs. 5th: $p < .001$; 1st vs. 6th: $p < .001$). Specifically, the score increased from the baseline test to the second test, maintained stable between the second test and the fifth test, and finally increased again from fifth test to the sixth test ($p < .01$). Different pattern was observed in service leadership beliefs. Compared with the baseline, only the scores of second, third and sixth tests were higher (1st vs. 2nd: $p < .01$; 1st vs. 3rd: $p < .01$; 1st vs. 6th: $p < .05$). Specifically, the score increased from the baseline test to the second test, but then maintained stable from the second test to the final test. These findings suggested that the programme was effective to enhance service leadership qualities and maintain them at a relatively high level. However, it seems more difficult to boost the level of service leadership beliefs, probably because the baseline was quite high.

DISCUSSION

Student development in tertiary education refers to “the application of human development concepts in postsecondary settings so that everyone involved can master increasingly complex developmental tasks, achieve self-direction, and become interdependent” [22, p. 3]. It is concerned with the development of the whole person and stimulation of positive growth in students [23]. The GYLP is not merely a leadership development programme – it is a programme that targets holistic development among students. As evidenced by the 12 dimensions of an effective service leader, the Service Leadership and Management Model aims to nurture a holistic set of competencies, which would allow students to provide high-quality service in this interdependent world. The service leadership model coincides with existing wellness models targeting to enhance individuals’ wellbeing. For instance, the empirically-based Model of Wellness [24] postulated that individuals’ total wellness comprises of healthy development in five self domains, namely the Creative Self (e.g., being mentally active, emotional awareness and expressivity, control); Coping Self (e.g., stress management, a sense of self-worth, realistic beliefs); Social Self (e.g., connecting with others, having empathy, ability to trust and love); Essential Self (e.g., spirituality, self-care, gender and cultural identity); and Physical Self (e.g., exercising, eating healthily). Taken as a whole, our findings showed that the GYLP influenced the participants positively in many of the aforementioned dimensions and beyond. Students’ positive youth development competencies including cognitive behavioral competencies, positive identity,

and general positive youth development qualities significantly increased when comparing the 1st and 6th wave. Similarly, service leadership competencies, and life satisfaction also improved.

The present findings suggest that more programmes similar to GYLP should be developed which would benefit students in different ways. First, regarding employability and leadership challenges, Clarke [25] reported on the present “soft skills crisis”, referring to the phenomenon where employers believed that young people are ill-prepared for the world of work, and lack soft skills such as communication, resilience, and the ability to work in teams. “Survey after survey is employers saying qualifications are important, but that just as important to us are so-called soft skills, character skills, the ability to get on with different people, to articulate yourself clearly, confidence, grit, self-control. They are saying we are not seeing enough of this in kids coming out of school” [26, para. 6]. Therefore, contemporary leadership theories and development programmes should include components to equip graduates with the very much needed soft skills.

Second, compared with the general population, university students reported higher levels of psychological issues [27]. In the US, suicide is the second lead cause to death of college students [28], and 14.9% of students reported having been diagnosed with a depressive disorder during their college studies [29]. In Hong Kong, worrying trends in suicide have been observed. Since the start of 2015-2016 academic year, an alarming number of 22 young people have taken their lives. Experts have attributed the phenomenon to the high-pressure education system and low levels of resilience against problems and stress [30]. Furthermore, the annual World Happiness report revealed that Hong Kong’s ranking in the United Nations’ global ranking of happiness dropped to its lowest ranking 75th among 156 countries and territories examined. “Hong Kong is losing a lot of competitiveness in terms of social conditions. We are trying our best to develop our economy at the expense of social life” [31]. This further reiterates the dire need and essence of holistic student development. Educators should strive to develop programmes that aim to prepare students to become service leaders in this competitive arena; but not in the expense of the development of intrapersonal and interpersonal competencies, as well as general life satisfaction. The present findings are also consistent with the previous with evidence that Service Leadership education can help students develop effective service leadership qualities based on objective outcome, subjective outcome, and qualitative evaluation [e.g., 8, 32, 33] studies.

While the findings from the objective outcome evaluation of the GYLP provide evidence to support the effectiveness of the programme in nurturing students’ service leadership, positive youth development competencies, and enhancing their life satisfaction, there are some limitations to the study. First, the evaluation was conducted using self-report assessment, which some scholars claimed may be subject to social desirability bias. However, according to Paulhus and Vazire [34], this is seldom a problem in research if well-established instruments are administered as in the case of our present study. The instruments we administered have been validated and widely used among tertiary students with high psychometric credibility. Second, respondents included only the participant themselves, thus providing us with a single source of evidence. Adopting a multi-informant approach to solicit data from participants’ peers or family would provide additional support to corroborate with our findings.

Although there is no consensus within the literature on a particular method that is most effective in leadership development among tertiary students, findings from the objective

outcome evaluation in the present study provide evidence to support the effectiveness of the GYLP, targeted to enhance tertiary students' service leadership, positive youth development competencies, and life satisfaction. Tertiary institutions globally may model after the GYLP in developing leadership programmes to prepare students to meet the challenges and needs in contemporary service economies. Highly autocratic, directive, and transactional leadership styles are dated [35]. Service leaders should be equipped with leadership competencies, caring dispositions, and moral competence. As quoted by Simon Sinek [36], renowned expert in leadership and management:

"The best leaders are those that understand the meaning of service, those who are willing to sacrifice for their own people."

ABSTRACT

Break the Cycle of Children's Environmental Health Disparities (Break the Cycle) is an annual collaborative interdisciplinary research and training program involving university students in academic tracks that focus on the impact of adverse social, economic, environmental and political factors on children's health, development, education and prospects for their future. The target populations are communities where there is a substantial measure of poverty associated with social and political marginalization predisposing to environmental degradation and risks to children's health and well-being. Each participating student is required to develop a project that focuses on preventing or reducing adverse environmental factors or their impact, in order to improve the health of the children who live in these communities. At the end of the project, students are required to present their studies and findings at a national conference and write manuscripts on their projects, which are then published in a journal supplement as well as a book. The projects cover a range of social, economic, environmental and political factors that operate over the lifespan, and have an influence on individual, family, community, and societal perspectives with an intergenerational implications. Most importantly, they add to our knowledge about children's environmental health disparities and propose solutions to reduce and eliminate health disparities and promote health equity for all children.

The papers in this publication represent the work of students who participated in the 14th Annual Break the Cycle program. The phrase 'break the cycle' in this context uses the ecological construct of the cycle of environmental health disparities, and represents a framework for projects and programs that reduce health disparities and promote health equity among children who are vulnerable as a consequence of adverse social, economic, environmental and political factors. The student projects are intended to 'break the cycle' and liberate children from the intergenerational cycle of health disparities, so they can grow and develop to their full potential. Through this academic process, the students gain knowledge, insight and skills to enable them to advance in their careers and become future leaders

INTRODUCTION

Children who grow up in poverty are more likely to be exposed to multiple adverse physical, chemical and social elements in their environment and more likely to be emotionally stressed, with multiple elements of insecurity with anxiety and fear [1]. They are more likely to be exposed to poor indoor air quality, which increases the risk for asthma and respiratory disorders, and are more likely to be living in older houses with high lead levels from old paint and plumbing which can result in brain damage [2]. In addition, the children are at risk for a variety of other environmental exposures, because poor neighborhoods are more likely to be located near roadways where the air is more heavily polluted with exhaust from motor vehicles, or near factories and even near toxic waste sites. Their neighborhoods and schools are often characterized by evidence of general degradation, they are more likely to be littered with trash, are poorly lit at night which increases risks of crime with fear of assault and a greater likelihood of having street drugs and drug dealers, with little to no green spaces and suitable facilities for recreation [3]. Furthermore, the emotional toll on the children from multiple stressors, including food insecurity, housing insecurity, and fear of physical injury from neglect and abuse which, cumulatively can result in the physiological phenomenon of chronically elevated cortisol levels and “toxic stress” [4]. The toxic stress syndrome is associated with unfavorable structural and functional changes in the brain, resulting in life-long consequences that can be associated with a reduction in brain volume in white matter, in grey matter, and specifically in the hippocampus and amygdala [5]. As they reach adolescence, these children are more likely to experience school failure and engage in risky behavior, including substance abuse, gang membership, and crime which can result in incarceration or death from drugs or gun violence. The elevated cortisol levels associated with toxic stress also have a metabolic and hemodynamic impact on the cardiovascular, immune and hormonal systems, resulting in an increased likelihood of adverse health outcomes in adulthood including obesity, diabetes, and hypertension, with their associated morbidity and mortality [4].

These risks for children are greater than they are for adults, because children breathe more air, drink more water, and eat more food for their body weight than adults, so their exposure load through polluted air, water and soil is greater. Furthermore, their organs and organ systems as well as physiologic and metabolic processes are still in development, so they are more vulnerable to immediate and long term negative health outcomes [6]. By the same token, the developing embryo and fetus is even more vulnerable to adverse environmental factors because the organs and organ systems are in an earlier stage of development. Therefore, the exposure of pregnant women to environmental toxins as well as emotional stress not only affect the pregnant mother's health and well-being but can also have serious and permanent effects on her fetus [7]. Despite the physiological protective elements in the placenta, many toxins enter the fetal circulation and can affect organ system development, anatomically and physiologically. Many substances can cross the blood-brain barrier and adversely affect the developing brain, resulting in disorders of development and learning with risks for learning disabilities, ADHD, and even autism [8].

Children from low income and minority communities tend to live in poor neighborhoods and attend older, more dilapidated schools, with teachers who are also suffering from the stress of adverse environmental factors. Thus, the combined effects of adverse environmental

and emotional stresses, along with negative educational experiences, compromise learning and even desire for learning or appreciation of the value of learning, which results in high drop-out rates and low graduation rates [9]. Limited education leads to poor employment opportunities, or work with low pay, trapping the young people in the poorer neighborhoods with the older houses in states of disrepair, contributing to exposures to indoor hazards of lead, mold, and other possible contaminants, as well as emotional stress with depression, anxiety about the future with despair and social isolation [10]. Those young people who drop out of school and have limited employment options with a relatively dim view of their future, may resort to drugs to feel better or crime to make money in order to live or support their habits or lifestyles. These behaviors can result in incarceration with the emotional and social consequences for the individual, the family, the community and society [11]. This scenario plays out in too many cities and states in the USA and, along with draconian drug laws, has resulted in the highest incarceration rate in the world with a high percentage of young men of color in prison [12, 13]. On a positive note, the statistics show that since the peak in the 1990s, the number of juvenile justice cases has decreased substantially. Although this positive trend is a result of factors beyond our personal control and reside in the hallways of local, state and federal processes, we can be encouraged to take action and strive to make a positive difference in the lives of vulnerable children, not only in reducing the negative environmental factors, but in promoting resilience through education as well as emotional and social support [14].

Figure 1. Cycle of environmental health disparities [15].

The assault of adverse social, economic and environmental factors on vulnerable children that results in unfavorable health, developmental, and educational outcomes, and compromises a child's opportunity for economic and social success in life, devolves into the perpetuation of an intergenerational cycle. It is the codification of this ecological construct that embodies the concept of the cycle of children's environmental health disparities (see Figure 1).

BREAK THE CYCLE PROGRAM

"Break the Cycle of Children's Environmental Health Disparities" (Break the Cycle) is an annual, collaborative interdisciplinary research and training program involving university students in academic tracks that focus on the impact of adverse social, economic, and environmental factors on children's health, development, and education. Each participating university student develops a project that focuses on preventing or reducing environment-related disorders for vulnerable children who live in communities where environmental hazards and emotional stresses are related to circumstances of social and economic disadvantage. At the conclusion of the project period, the students present the results of their projects at a national conference and write manuscripts on their projects which are then published in a journal supplement dedicated to the collection of projects from each given year [16]. Each annual program begins with a call for proposals from a wide range of university students. The proposals are then evaluated by a competitive review process for the quality of the proposal, its relevance to children's environmental health disparities, creativity, and feasibility. The 10 best proposals are selected to work with their academic mentors and their home universities and with the Break the Cycle faculty to complete their projects. The students and their mentors are required to participate in monthly conference calls, during which the progress of each project is reviewed, additional perspectives are explored, and constructive guidance is provided. During these conference calls, the students and their mentors also have an opportunity to communicate and collaborate with their counterparts at other universities.

Table 1. Project guidelines

- | |
|--|
| <ul style="list-style-type: none"> • University faculty identify students who have an interest in this topic area and support the student in the selection of an idea for projects that explore environmental factors that adversely affect the health of children living in circumstances of social and economic disadvantage. Alternatively, students interested in a specific project can initiate the application process and identify mentors to work with them. • The students submit their proposals which are reviewed by the <i>Break the Cycle</i> faculty. The process is competitive with only 10 projects being selected each year. • During the project period, there are monthly conference calls with all students and mentors to monitor the progress of the projects, share ideas, and assure that the projects are consistent with the spirit of the <i>Break the Cycle</i> concept. • At the end of the project period, the students present the results of their work at the annual Break the Cycle conference. • The students are then required to write papers on their projects, which are submitted for publication in an international journal as a monograph of the <i>Break the Cycle</i> projects. The papers are also published as chapters in a book. • The progress and careers of the participating students are tracked to evaluate the impact of their participation in the <i>Break the Cycle</i> program. |
|--|

When the program was started, the expectation was that the projects would make a positive difference by improving the health and well-being of children, their families, and their communities. It was also envisioned that students would be inspired to pursue careers that focused on reducing health disparities and in becoming leaders for the future. Furthermore, because each student is required to have a mentor at their home university, it was anticipated that the faculty mentors would add to the literature and body of science on the subject into their curricula, and thereby promote further research and academic interest in this field (see Table 1).

Table 2. Desired outcomes

• To inspire students from a variety of academic disciplines to explore the impact of adverse social, economic, environmental and political factors on the health, development and education of children, and to creatively generate strategies to address the challenges. • To collaborate with an interdisciplinary team of academic leaders from a variety of different universities and colleges to get a perspective on the broader issues of this topic area • To encourage faculty at universities who participate in this program to promote academic interest and social awareness in children’s environmental health disparities • To cultivate future leaders among the students

We also expected that the participating students would inspire peers in their academic, social and professional circles, and that the interdisciplinary nature of the program with participation of students at other universities around the world, would be stimulating and inspiring (Table 2). The 2012 survey of alumni of the program showed that the students derived significant benefit from all aspects of their participation in the process, which included the practical aspects of conducting a research project, experience in preparing and delivering a presentation and writing a manuscript. Each student gained knowledge about children’s environmental health and environmental health disparities as well as being exposed to different perspectives from the other student projects [16].

Since its inception in 2004, Break the Cycle has held 14 annual programs and worked with over 120 students representing 30 different university departments in 10 states in the US, as well as students from countries in Latin America, Europe and Africa. To date, 11 monographs have been published in international journals and 11 books in a public health series. In the 2012 survey, the students rated their experience with Break the Cycle as valuable, many reporting that they pursued careers relating to their Break the cycle projects [16].

BREAK THE CYCLE 14 PROJECTS

The papers in this publication represent the interdisciplinary array of creative work by students from universities in six states in the US who participated in the 14th Annual Break the Cycle program in 2019. As usual, the papers in this volume cover a wide range of topic areas including the critical importance of maternal child relationships, adverse childhood experiences, communities, neighborhoods and gentrification, lead in drinking water, disparities in autism and systemic lupus erythematosus (SLE) diagnosis and treatment, and two new topic areas: one on the American Indian experience and the other on Medicaid

coverage. While the projects on the more familiar themes add to our appreciation and understanding of the conditions addressed, the two new topic areas challenge us to think afresh about the complexity and scope of the concept of children's environmental health disparities. In addition, we identified themes across the projects, which are:

- *Cost of care.* Healthcare financing is a critical factor in assuring access to quality diagnostic and therapeutic services. This is the focus of the student project in this series on expansion of Medicaid services and health outcomes, but it also has relevance across other projects, such as access to services for children with autism. There is no question that Medicaid has improved access to healthcare for vulnerable populations in our society, particularly for children from low income families, but there remains room for improvement at a systemic level.
- *Literacy and health literacy.* The importance of speech, language, communication, and understanding of the spoken and written word in health and healthcare is essential. The projects that address this topic area range from the importance of infants being exposed to complex speech and learning vocabulary early in life, to the importance of health literacy of mothers in taking care of their infants, to teenagers with SLE being able to read and interpret the doses of their medication. Ultimately, this speaks to the importance of a good general education as well as being educated about wellness and maintaining good health.
- *Neighborhoods, communities and culture.* Our neighborhoods and the communities are the building blocks of our society. Projects in this series examine the specific communities of American Indian pregnant women and the young mothers of infants from Paraguay, which effectively opened the conversation to exploring cultural identity and how to effect positive change without losing sight of the respect for the importance of cultural history and cultural ties and how these affect health literacy and healthy practices. In addition, there are the African American communities in North Carolina which are geographically isolated from municipal water resources and must rely on well-water which is more likely to be contaminated. Then there are the low-income communities living in degraded neighborhoods which are undergoing transition to an upgraded and more upscale built environment. As a consequence, families in the old neighborhoods are required to adapt to the changing environment and demographics or forced to relocate; either way there is disruption of their communities with adverse social and emotional consequences.
- *Individual vs population or statistics.* The values of science and its practical translation for use in real life are critical to our understanding of ourselves, the environment, and our interaction with the environment. While statistics are the foundational basis of our science today, the appreciation of the findings may not be readily apparent in real life. In several of the papers in this series, most notably in the two on autism disparities and the work on the mothers in Paraguay, there are vignettes of what some of the subjects reported of their experiences. These vignettes help to breathe life into the science and help in conveying an understanding of the findings and their implications.

The following are brief reviews of the Break the Cycle 14 student projects in this volume.

The Development of a Prenatal Care Health Literacy Instrument for American Indian Mothers

This project is the first in the 14 years of Break the Cycle to focus on the American Indian community. As of 2017, there were an estimated 5.6 million people who were classified as American Indian and Alaska Native comprising 1.7 percent of the total US population [17]. American Indians were on American continents for millennia before the European conquerors arrived and decimated the large Native American population with unfamiliar diseases, and with sophisticated weaponry and strategies honed from the frequent and often protracted battles and wars fought on European and Asian soil. After countless battles and wars between the European settlers and the Native Americans, so-called treaties partitioned American Indian land into fragments for each of the remaining tribal groups scattered across the continent, disconnected from one another. This disconnection had some basis in the different identities and cultures of the extant tribes at that time and may have seemed logical, but the dispersion and local tribal affiliations has precluded a cohesive and compelling coalition that, theoretically could, by virtue of a unified voice, become a force to be reckoned with, politically and economically. Furthermore, the conquering armies and immigrant people exerted power over the indigenous population through subjugation with systematic and determined disruption and destruction of the existing cultural norms, languages, practices and beliefs, and through the imposition of the conquerors' culture, language, customs and beliefs.

Consequently, the people who once proudly and powerfully populated and dominated the American continents, effectively became and, even in the 21st Century, remain second class citizens. In the US, they have become a relatively forgotten and neglected people. Apart from the imagery and pageantry, American Indian communities remain in remote and disconnected parcels of land, in situations of social, economic and political isolation. As a result, unemployment, poverty and despair result in the ills of the people and their society, effectively trapped in the cycle of environmental health disparities [17, 18]. However, despite the prevailing poverty, lack of good education and healthcare services, high unemployment, as well as other adverse economic and social factors, there are positive trends with modest individual and group successes. In his book on the resilience of the American Indian Community, David Treuer reviews and revises the history of the people as has been told over time to the present, and builds a picture of a proud and resilient group of people who have survived the genocide and are rebuilding their identity and defining their role on the global stage [19].

There is much work to be done to improve the situation for most people of Native American heritage and to rebuild their communities, their educational institutions, and the provision of healthcare, especially for the children. To this end, the United States Centers for Disease Control and Prevention (CDC) is working with relevant agencies to foster cooperation and promote good health [20].

In her project, Jordyn Gunville, MPH, from the Center for American Indian Community Health, Department of Family Medicine, at the University of Kansas Medical Center, focused on the high infant mortality rate among the American Indian population, which is nearly four times that for white infants. She examined the role of education and health literacy in promoting a healthy attitude towards pregnancy and prenatal care in not only reducing infant

mortality, but also in cultivating a healthier approach to childbearing and childrearing. She makes a very persuasive argument that a focus on literacy and health literacy are crucial to improving awareness of health for the mother, for the child and for the community and for the society at large. The long-term outlook for this approach lies in a positive trans-generational impetus to improved health, improved education, and improved family, community, and societal stability. The next step in the process is to develop strategies to raise awareness in promoting policies and implement practices that will reduce infant mortality and measurably improve child health and education. This student has demonstrated that promoting literacy and health literacy brings substantial benefit in the promise of breaking the cycle of health disparities, particularly for this population.

Barriers and Opportunities for Young Caregivers to Provide Nurturing Care in Low Income Communities in Paraguay

Although we have previously had student projects from Central and South American countries, including Chile, Mexico and Brazil, this is the first from Paraguay. The population profiles of each of the Latin American countries is unique, yet there are themes and patterns common to all [21]. Prior to the European invasion, as in North America, the lands were populated by native tribes, communities with political and economic powers, including great civilizations and empires. The European settlers and conquistadors overpowered and overwhelmed the local peoples with wars, and subjugated them with oppressive policies. At times, there were conflicts and even battles and wars between neighboring countries. Over time, each of the Latin American countries has undergone political changes and upheavals as well as political convulsions and revolutions, cycling through various forms of government, including dictatorships, until eventually settling, for the most part in the 21st century, into relative democracies. The reality in many Latin American Countries is the wide gap between the rich and the poor as measured by the Gini index [22], which is an international measure of economic inequality in a particular country. The lower the score, the more equitable the income distribution. Few regions in the world are as unequal as Latin America [23]. Out of the 20 countries worldwide when measuring high income inequality on the Gini Index, eight are Latin American while the rest are in Sub-Saharan Africa. On a positive note, Latin America is a region to have made the most progress in attenuating wage inequality since the turn of the century, lowering its Gini index by 6 points from 2002 to 2013.

In her project, Jimena Vallejos MPA, studying at Columbia University School of International and Public Affairs in New York, focused on early childhood development and examined child rearing practices in poor neighborhoods in Paraguay using the WHO/UNICEF/World Bank document entitled *Nurturing Care for Early Childhood Development: A Framework for Helping Children Survive and Thrive to Transform Health and Human Potential* [24]. In her project, she interviewed families and catalogued their knowledge, child rearing practices, and the challenges they face.

She also listed the various agencies and policies that have been developed in response to the situation in Paraguay, and made some specific recommendations of her own, most importantly to focus on the families, strengthen the services, monitor progress and keep track

with data to validate the outcomes. This is another strong example of a student project making a difference and offering practical strategies to break the cycle.

Breaking the Cycle of Childhood Adversity through Pediatric Primary Care Screening and Interventions: A Pilot Study

Although the association between chronic disorders and illnesses in adults with early childhood traumas has been documented, it was not until a large study of almost 10,000 subjects from a large health maintenance organization (HMO) in collaboration with the Centers for Disease Control and Prevention (CDC) was published in 1998, that the codification of Adverse Childhood Experiences (ACEs) was clearly linked to adverse health outcomes in adulthood [25].

This study linked a set of 10 ACEs in childhood categorized as reflecting abuse, neglect or household dysfunction and characterized as physical, emotion and sexual abuse or physical and emotional neglect; household dysfunction include mental illness, substance abuse, domestic violence, family disruption, or a family member who is incarcerated. The physical and physiological adverse health outcomes they identified were, metabolic disorders such as obesity and diabetes, cardiac disorders and stroke, chronic lung disease, as well as increased likelihood of broken bones and cancer, all reducing life expectancy. They also had an increased likelihood of patterns of substance abuse, with addictions to tobacco, alcohol, eating, sex, and to drugs such as opioids, all with consequent risks of early death. They also identified a greater likelihood of depression with increased risk for suicide attempts and successes. Furthermore, the patterns of mental and physical disorders make it less likely that they would hold a steady job, resulting in reduced income and increased likelihood of dependence on public welfare. In all, not only did ACEs lead to adverse health, behavioral and social outcomes aggravating the stress on the individual and family, but also on the community and society at large.

Furthermore, the study found a positive correlation between the number of ACEs and the number and severity of adverse health outcomes, especially with those who experienced four or more ACEs compared to those who had experienced none. For example, they found 4- to 12-fold increased risk for alcoholism, drug abuse, depression, and suicide attempt; a 2-to 4-fold increases in smoking, poor self-rated health, having more than 50 sexual intercourse partners, and sexually transmitted disease; as well as a 1.4- to 1.6-fold increase in physical inactivity and severe obesity. The intergenerational consequences are likewise profoundly disturbing – see the cycle of health disparities (see Figure 1).

At the 12th annual Break the Cycle program, there was a symposium on resilience during which one of the presenters, a woman who had a high childhood ACEs score, spoke about her childhood and resultant physical, emotional and social disorders of her adulthood, and how she overcame them to find a job at the CDC working the field of ACEs [14]. The lessons from her life story illustrate how people can overcome ACEs and develop resilience to become successful, functioning and healthy adults.

Importantly, the project by Cristian Quizhpi, MD, a pediatric resident in the Department of Pediatrics at East Tennessee State University, looks at how ACEs and their consequences can be identified at an early age through screening and intervention in primary care pediatric

settings and strategies can be developed to increase the likelihood that the children being seen in infancy and childhood will escape ACEs and grow up will become healthy, competent, functioning and independent adults who make positive contributions to society.

Figure 2. The CDC ACE pyramid [26].

Educating Clinic Stakeholders to Enhance Early Learning Environments through Pediatric Well-Child Visits

The human brain enables sophisticated levels of cognitive and intellectual function, especially with communication and socialization. Most of brain development in the proliferation of numbers of cells, in migration of neurons to their place in the cerebral cortex and with the formation of a network of connections between the neurons, occurs before birth. After birth, the major factor in brain development is in the myelination process, which contributes to brain growth in size as well as physiologically enhancing the speed of neural transmissions facilitating thinking processes and helping to provide the increasing physical, cognitive and social abilities that will serve as a basis for independent functional and social living. The next critical element in brain growth and development is in utilizing the infrastructural elements of the brain in the process of building competence, confidence and independence through enhancing neural connections and networks. While much of the brain development is genetically determined, there are powerful environmental forces at play, prenatally as well as postnatally, that influence all aspects of brain development, especially in the development of neuronal connections directly or indirectly through epigenetic mechanisms [27].

It is during these first three critical years of brain development when environmental factors play the largest role in brain development in positive as well as negative ways. Just as

adverse childhood experiences have a profound negative effect on brain structure and function, positive influences such as maternal-infant bonding, intense mother-child interaction, parental communication around the child and with the child, and reading to the child frequently, have a positive effect on the child though the positive effect on brain function, resulting in greater chances of maturation, independence and success in life [28].

In their project, Cori Walker, a medical student at the University of Chicago, and Asher Liu, a high school student, partnered to raise awareness in pediatric offices of the importance of promoting parent-child interaction towards improving the child's experience of language and promote enhanced language development. This project was supported in part by the Thirty Million Words (TMW) program, which has as its premise that children from high income families will hear 45 million words by three years of age, while the three year-old of a low income or welfare family will only hear about 13 million words, a gap of about 30 million words [29]. The goal of the TMW program is to reduce that gap, and the project by these two students demonstrated that a primary care pediatric office is a good place to start, with the encouragement of stimulation of infant speech development. Similar programs like "Reach Out and Read" also focus on primary care pediatric offices to promote reading among low income children [30]. Each effort at increasing literacy for children, in encouraging children to read and communicate effectively, plays a part in increasing the promise of success in life, thereby contributing towards breaking the cycle of children's environmental health disparities.

Engaging Parents of Children with Autism Spectrum Disorder to Identify Urban and Rural Health Disparities and Factors Related to Delayed Diagnosis and Treatment and Autism Disparities: Structural and Institutional Barriers

Autism spectrum disorder (ASD) is the current term used to diagnose children who have a neurodevelopmental disorder characterized by delays and unusual patterns of speech and language development, and unusual patterns of communication interaction and socialization, along with a need for sameness, with obsessions or repetitive behaviors. An ASD diagnosis manifests in a large range of differences in complexity and severity of the symptoms – hence the use of word "spectrum" in the diagnostic label.

The diagnosis has evolved since the first description in 1943 by Leo Kanner (1894-1981) of infantile autism [31], then, over decades, the less dramatic expressions became characterized as pervasive developmental disorder of childhood, through the inclusion of Asperger syndrome describing children who were verbal and intelligent, sometimes extraordinarily intelligent, often with a singular focus of interest. Interestingly, Hans Asperger (1906-1980) wrote his paper in 1944 [32], but because it was written in German, it only came to clinical attention in the USA after it had been translated into English in the late 1980s [33]. Over the course of the decades since the original description by Kanner in 1943, almost 80 years ago, the number of children who have been diagnosed has grown from one 1 in 10,000 in the early decades to 1 in 150 in the CDC report of 2002, to 1 in 59 in the CDC report of 2018 [34]. Part of the increase in prevalence is certainly the expansion of the diagnostic umbrella, but there may well be a real increase in prevalence, likely related to genetic and

epigenetic factors precipitated by the profusion of chemicals in our environment [35, 36]. Be that as it may, it is critically important to make an early diagnosis and institute therapy as soon as possible, to improve functional outcome and reduce complications [37].

Two student projects this year looked at disparities for children with ASD with delays in diagnosis and limited initiation of therapy related to type of insurance coverage and to geographic location. Alice Hong, a student at Georgia Institute of Technology, School of History and Sociology in Atlanta, Georgia, looked at low-income minority families, often in a single parent household, on public health insurance. Amy Blumling, a student at Emory University Nell Hodgson Woodruff School of Nursing, looked at low income rural populations. In both cases, there were delays in diagnosis and difficulty in accessing necessary services. In both projects, students' methodology reviewed the demographics and other characteristics, but explored individual circumstances of the families, providing not only the statistical information on the situation but delving into the personal and real-life challenges and emotions, as well as coping styles of the families. Both provided a rich insight into the lives of these two groups of families and communities and generated a sympathetic set of recommendations and strategies to reduce these disparities. Since the situation is not uncommon in lower income, often minority, families, a Break the Cycle of Autism Disparities Program was started, which promises a systemic look at how to improve the access to timely diagnosis and appropriate therapies [38].

Water Infrastructure and Childhood Blood Lead Levels: Characterizing the Effects of Exclusion from Municipal Services in Wake County, North Carolina, USA

Water is an essential part of life and access to clean drinking water is at the core of the Sustainable Development Goal #6 of "clean accessible water for all." A driving force of the goal is a call for "increased investment in management of freshwater ecosystems and sanitation facilities on a local level in several developing countries" [39]. In the US, there is substantial pollution of many bodies of water, most notably in the Great Lakes, which was, in the early 1970's, the impetus for the Clean Water Act [40].

Allison C Clonch, a Public Health student at the Gillings School of Global Public Health at the University of North Carolina, Chapel Hill, demonstrated the presence of increased lead in well water in poor African American neighborhoods in North Carolina. Lead is toxic to children and often causes brain damage, placing the children at a disadvantage academically and socially thereby contributing to the cycle of environmental health disparities [41]. The families in these communities use well water because their districts have been excluded from municipal water supply. This is the 2nd project from this academic center looking at the impact of this discriminatory practice in not providing municipal water to a community, thereby putting children at significant risk for the immediate and long-term adverse health outcomes of lower quality than that of the municipal water [42]. Raising awareness of this situation is the first step in breaking the cycle. The next step is to change the situation by restructuring the water supply. The student appropriately asks for "more regulatory oversight and water quality tests of private water systems or facilitating access to municipal supplies in order to mitigate the impacts associated with childhood lead exposure."

Self-Reported Neighborhood Quality and Children's Depression Symptoms in a Gentrifying Northern Manhattan

Gentrification refers to the process of change taking place in an older, low income, often minority and most-likely degraded neighborhood, when relatively wealthier residents and businesses move into the neighborhood because of the lower rent and opportunity to build, restructure and grow [43]. The initial influx is gradual but over the course of time, the trickle becomes a flow and at some point, the neighborhood is transformed from the old, often dilapidated and neglected character, to a modern, often creative one, with desirable amenities such as restaurants and boutiques that attract new, more affluent residents and visitors. Often a large chain business will anchor in the neighborhood, offering the local residents access to more amenities and products with further income generation for the area making it more affluent and desirable for the residents. For those moving into the neighborhoods it is exciting and promising, and for the business it can be lucrative, but for the long-term residents for whom the neighborhood has long been home, and the community a source of support and identity, the change may not be positive and can be disruptive.

The anthropologic history of cities and neighborhoods is one of flux. Cities were often established based on access to transportation routes, or near a sizable waterway for water supply and transportation. As cities grew and flourished, they often became overcrowded and required some strategy to deal with the growth. In the US, as in other parts of the world, the arrival of the automobile altered the patterns of urban living dramatically. When transportation was limited to pedestrian or horse driven vehicles, proximity to the necessities of day-to-day life was a critical determinant of residential location. However, with the advent and increasing availability of the automobile, proximity became less important because people could live some distance from the city and drive to work. Thus, began the suburbanization of society. The migration of people with financial means to purchase homes and cars to the suburbs led to dramatic suburban growth. The resulting vacant urban residential areas provided an opportunity for people of lower income to settle and find work for themselves, schools for their children, and communities of people like themselves to provide the social and emotional support necessary for health and stability [44]. Unfortunately, over time, inner cities became concentrated with low income families and communities, while their more affluent counterparts were living in the suburbs. This situation became informally institutionalized, if not codified and calcified over the course of the early second half of the 20th century [45]. Then, towards the end of the 20th Century, for a variety of social and economic factors, younger people with means began to move back to the cities and started the trend of gentrification, which continues today in many large cities in the US [43].

In her project, Teresa Durham, at the Columbia Center for Children's Environmental Health, Columbia University in New York City, examined the impact on the health and well-being of children in the rapidly gentrifying neighborhoods in Northern Manhattan. The Columbia Center has been working in this neighborhood for many years, tracking the children and families, and has collected data on the impact of gentrification on the community in Northern Manhattan, which their students are now mining. A prior student from the Center who had participated in the Break the Cycle program looked at the impact on children's health focusing on children's nutritional status [46]. In her work, Ms. Dunham focused on the

mental health of the children, particularly anxiety and depression. She found that although anxiety was a common symptom, it was not greater than the baseline level of anxiety of children in the neighborhood under stress. She did, however, find a level of depression greater than baseline among the children. Of interest, her results revealed that the children who exhibited the symptoms of depression were those whose mothers rated their total neighborhood quality as being more stressful over a six-year time period than the children of mothers who reported their neighborhood to be less stressful. This study helps us to recognize the importance of understanding the experience of stress and its manifestation in anxiety and depression in children, and the management of stress as important in promoting health for the children. It is also helpful in determining interventions for the children and their families when a neighborhood is undergoing such dramatic upheaval and the anticipation of a possible move from the familiar and comfortable home and neighborhood environment, to an unknown destination. The question to be asked is whether the measure of stress reported by some of the mothers was a valid reflection of overall neighborhood stress, or the stress was personal and was associated with other factors within the family in terms of coping mechanisms and resilience, which could then affect her children. In addition, communities must consider their collective and individual responsibilities to be aware of the impact of gentrification on children's health and development and to help prevent the inevitable associated health impacts, such as anxiety and depression [47].

The Impact of Childhood Exercise and Socioeconomic Status on Coping Strategies and Resilience in College Students

It is well recognized that children from lower socioeconomic circumstances are less likely to attend college and, if they do, they are less likely to graduate and less likely to attend a post-secondary school of higher education. The statistics are difficult to refute and extremely sobering – see the Figure 3 below [48].

Figure 3. Among 2009 ninth-graders who had enrolled in postsecondary education by 2016, percentage distribution of selectivity of students' first postsecondary institution, by socioeconomic status [48].

Among several reasons given for this phenomenon, one pragmatic reason is that primary education is not as effective or at a level of similar quality in poorer neighborhoods, where the children and their families have less financial resources and the children may need to work to sustain income and pay for college. Other reasons relate to a 'sense of self' or self-esteem and appreciation of one's capability and potential.

In her project, Leah Postilnik, BSN, a student at the College of Nursing, University of Massachusetts, examined the role of exercise and physical activity as a factor in shaping resilience in those students from communities of lower socioeconomic status (SES). Although there are fewer students from lower SES communities who attend college, and, of those who do attend, a significant number who do not complete their courses, there are students with a background of low-SES who do attend college and university and who do thrive and succeed. Students from low-SES background who do succeed do so because of an ability to overcome adversity through resilience. The factors that determine resilience may be genetic and inherent in the personality of the individual, but include environmental and experiential elements as well, most significantly is the presence in their lives of a caring, supportive encouraging, and committed adult, be it a parent, grandparent, other relative, teacher or parent figure in their communities [14]. In addition, social networks of support, positive role models, a good education, intellectual stimulation, self-discipline and positive, physical exercise also contribute significantly to the development of resilience. Ms. Postilnik examined the role of exercise in promoting and reflecting resilience and academic achievement, and found a positive correlation between resilience and exercise frequency. When controlling for other variables, college exercise was the only variable shown to predict resilience, and middle school exercise predicted high school and college exercise. Implications of these results suggest the need for interventions to increase exercise for children from low SES environments, establish exercise habits early in childhood, and use exercise as a tool to promote resilience. Exercise may not be the sole factor, but is a strong and positive force in promoting physical, mental, emotional and social health, which in turn promotes self-esteem and a positive approach to life and its challenges and break the cycle of health disparities.

Health Literacy in Pediatric Onset Lupus Erythematosus

Systemic lupus erythematosus (SLE) is a complex autoimmune disorder. It can affect many organ systems in the body as well as the brain, manifesting in psychiatric disorders. In more severe expressions of the condition, it can result in organ system failure, particularly renal. In all, SLE causes much physical and mental suffering and can shorten life expectancy. Because it affects many organ systems, the person with SLE is likely to need the expertise of a variety of different medical specialists as well as therapists and more often than not, require multiple medications.

This lifestyle of multiple physician and therapy visits, that consume significant hours in any day in travel and waiting in addition to the specific clinic visits, can be physically and emotionally stressful and draining of energy and time for education, recreation and socialization. The combination of the impact of the disease process and the stresses associated with the condition and its management, compound the situation. On a positive note, much research has been done to understand and manage the condition, reducing the likelihood of

complications and mitigating severity. Further, in recognition of the need for close monitoring of the condition and continuity of care, multidisciplinary clinics and centers have been established where people with lupus can go to get their necessary practical help and support that is configured to provide comprehensive, coordinated care to people with lupus, to monitor their progress, assure optimal care, and deliver as good physical, emotional and social health outcomes as possible for each individual.

Catherine Park, MD, a Fellow in the Department of Pediatrics, Division of Nephrology at Emory University School of Medicine, where she serves children with lupus, compared the clinical profiles of children from poor circumstances to those from more affluent backgrounds, and found that the poorer children were more likely to be diagnosed later than their more affluent counterparts, were more likely to be exposed to second hand tobacco smoke (which is known to aggravate the clinical condition), and tended to have more serious complications with more emergency department visits. She administered health literacy tests to the children, and found that the children from the low SES group had lower numeracy literacy than their more affluent counterparts. She postulated that the lower numeracy literacy possibly contributed to their increased rate of medical complications, because of their limited ability to accurately read the instructions on their often multiple bottles of medication, as well as to read the details on food labels. Although her sample size was small, the findings were significant, and reflect the importance of literacy and health literacy. In addition, this speaks to the critical importance of a good education for children, particularly for children from low SES background, with emphasis on fundamental skills such as reading and math, which better prepares them for life and its challenges, and helps them lead healthier lives and break the cycle of health disparities.

Although it is not addressed in this paper, the issue of cost of care and insurance reimbursement with Medicaid is a significant factor in the care of SLE. The condition is often complex and requires frequent, and expensive, specialized medical attention, with multiple medications and increase in emergency department visits, not to mention the incidental costs of transportation and lost hours at school or work for parents. While these costs may be reasonably borne by more affluent families with private health insurance, they are more likely to be burdensome for lower SES families and may seriously affect their livelihood. Fortunately, there is a safety net in publicly funded medical insurance through Medicaid, which helps to secure the necessary medical care, but not necessarily the incidental and collateral costs.

Did Medicaid Expansion Decrease Disparities for Receipt of Preventive Medical Care among Vulnerable Children?

In 14 years of Break the Cycle programs, this is the first student project that examines children's health insurance as a factor in breaking the cycle of children's environmental health disparities. In US society, where access to health care is dependent on the cost of health care and reimbursement to the providers of healthcare, the ability of a family to pay for the care becomes a powerful determinant in access to, and provision of healthcare, be it episodic, routine or long term. In the US, private health insurance is a critical resource to secure necessary healthcare. Families who can afford the cost of insurance premiums have

relatively easier access to quality healthcare. For low income families who do not receive assistance in covering the cost of health insurance premiums, there is Medicaid. Medicaid in the US is a federal and state program that helps cover medical costs for some people with limited income and resources.

The history of American society and government in developing and providing public health insurance through Medicaid, has evolved over the past half century from the establishment of health insurance for the elderly though Medicare established in 1965, based as a policy framework on the social Security Act of 1935. Over the decades, the benefits have been extended to an increasing list of vulnerable populations through the Home and Community Based Services (HCBS) Medicaid waiver programs, and more recently, the Children's Health Insurance Program (CHIP). The most recent evolutionary component of the Medicaid program has been the Affordable Care Act (ACA) of 2010, which expanded the services further (see Figure 4 for details on the evolution of Medicaid services). Of note is that the Medicaid program is a Federal-State partnership, and not all states in the US opted into the ACA.

In her project on whether Medicaid expansion resulted in improved healthcare to vulnerable children, Patricia Daniel, PhD, from the Center for Leadership in Disability, at Georgia State University in Atlanta, Georgia, compared data from those states that opted into the ACA and those that did not. Data suggest that Medicaid does contribute to improvement in health of the populations it serves, and Dr. Daniel was able to demonstrate this in her study. At the time of this writing, national political debate is examining the pros and cons of further Medicaid expansion, with some suggesting a universal coverage model similar to a number of Western European nations and Canada or complete abandonment of the ACA. Whatever the outcome of the debate, the important fact is that Medicaid covers one in five people in the US and is the main sources of coverage and access to healthcare for vulnerable populations. This is especially true for children, the elderly population, people with disabilities, as well as people with low or no income, who cannot afford private insurance; as such, it has been and continues to be of great benefit not only to the individuals and families served, but also to society at large [49].

Figure 4. Medicaid has evolved over time 1972-2015 [49].

CONCLUSION

As with our previous Break the Cycle programs, each student had identified a different component of the Cycle of Children's Environmental Health Disparities and highlighted the way in which the cycle can be broken at that point and the health of vulnerable children can be improved. In the process, the students benefited from creatively developing a project, translating it into action, performing the research, presenting the results of their projects at a national conference and now writing manuscripts for publication in this publication. In addition, their mentors, as well as their peers and we, the Break the Cycle Faculty, have also learned and benefitted from this collective experience. Furthermore, our society gains by their work in the present, and will undoubtedly gain in the future when this cohort of students become our leaders.

ABSTRACT

Every year natural disasters kill around 90,000 people and impact close to 160 million people worldwide. Natural disasters include earthquakes, tsunamis, volcanic eruptions, landslides, tornadoes, hurricanes, floods, wildfires, heat waves and droughts. When a disaster strikes, it has an immediate impact on the physical, biological and social environment with the destruction of property and disruption of human lives. Although a disaster is indiscriminate in whom it affects, poor and medically underserved people, minorities, people with chronic medical problems or disabilities, particularly children and the elderly, bear an unequal burden of the impact. During the initial surge, the health care

* Corresponding Author's Email: lrubi01@emory.edu.

system is immediately overwhelmed with injuries and acute illness needs, resulting in a sudden and dramatic increase in demand for emergency medical services. Following the initial surge, there are long-term consequences of disasters on the population as well as on the natural environment and the built environment, that have economic, social and political implications on health and wellbeing on individuals, their families, communities and societies. We will explore strategies to prepare for and to minimize the impact of the disasters, particularly on vulnerable populations, and advocate to reduce global warming which contributes significantly to the frequency and intensity of natural disasters.

INTRODUCTION

In this commentary we will present an overview of natural disasters and their consequences, and offer examples that serve to illustrate how different countries and different regions, as well as different populations and communities within a country, suffer disproportionately from the disasters. We will offer strategies in responding to disasters as well as disaster preparedness in order to mitigate the effects of the disasters on human populations, particularly the most vulnerable. In this context we will explore strategies to promote resilience for individuals and for systems to deal with the anticipation of disasters and for positive and constructive responses following the event. We will also address the role of climate change in the frequency and intensity of the natural disasters.

DISASTERS

A natural disaster is an act of nature of such magnitude as to create a catastrophic situation in which the day-to-day patterns of life are suddenly disrupted and people are plunged into helplessness and suffering, as a result, there is a need for medical and nursing care, food, clothing, shelter, and protection against unfavorable environmental factors and social conditions. The impact of the disaster takes a toll on the affected population with an increase in death rate, and with acute injuries and health impacts, as well as long-term physical, emotional and financial consequences for the affected individuals, families, communities and society at large. Every year natural disasters kill around 90,000 people and affect close to 160 million people worldwide [1].

Disasters are divided into two categories:

- *Natural disasters:*
 - Geophysical phenomena such as earthquakes, tsunamis, and volcanos,
 - Climatological/Meteorological conditions such as tornadoes, hurricanes, floods, and wildfires, as well as extreme weather events such as blizzards, droughts, and heat waves
- *Technological disasters* occur as a result of structural failures, such as factory explosions, fires, chemical spills, industrial accidents, transportation accidents, and nuclear accidents, as well as acts of terrorism and civil disturbances, with associated humanitarian refugee crises.

In this commentary we will focus on natural disasters although, as will be seen, there are often associated technological elements that complicate and aggravate the impact of the natural disasters. For the geophysical disasters, we will focus on Tsunamis and Earthquakes and for the climatological or meteorological disasters, we will focus mainly on hurricanes.

PREVALENCE AND CONSEQUENCES

In 1988, WHO established the Center for Research on Epidemiology of Disasters (CRED) to maintain an Emergency Events Database (EM-DAT) of disasters, with the objective of informing humanitarian action at national and international levels in order to improve rational decision-making in disaster preparedness, and provide objective data for assessing communities' needs [2].

In order to be recorded as a natural disaster in EM-DAT, an event must meet at least one of the following criteria:

- Ten or more people reported killed
- 100 or more people reported affected
- Declaration of a state of emergency or
- Call for international assistance.

While EM-DAT is the most comprehensive disaster database available worldwide, there may be some underreporting from certain regions such as from Africa. Be that as it may, the database reported that between 1994 and 2013 there were 6,873 disasters, which claimed a total of 1.35 million lives, with an average of 218 million people affected per year, during that 20-year period. Although earthquakes were the deadliest type of disaster accounting for 45% of deaths, flooding affected the highest number of people, accounting for 50% of the total affected [3].

Figure 1. Number of worldwide natural disaster events recorded between 1900 and 2018 [3].

Figure 1 represents the number of disasters per year from 1900-2018 showing the dramatic increase in natural disasters over the past 50 years [3]. This increase in rate and intensity of natural disasters is directly linked to climate change and global warming [4].

Furthermore, there are some areas of the world where particular disasters are more common, for example, along geophysical fault lines such as the Ring of Fire, which is responsible for more than 90% of the world's earthquakes [5]. The concerns around flooding are particularly in low-lying coastal cities such as occurred in New Orleans with Hurricane Katrina [6]. Some areas of the world are so densely populated that a disaster can take its toll on a larger number of people. Other vulnerable populations live in cities and countries considered poor, with limited financial resources and infrastructural services to prepare or manage the disasters. Members of all communities who are particularly vulnerable are children, older people, those with disabilities or chronic medical conditions, as well as minority populations [7].

Figure 2. Death rates from disasters in countries with different income levels [8].

Of note is that although the death rates from natural disasters has dropped dramatically because of disaster preparedness strategies, the highest rates of death occur in the poorest populations [3, 8]. Figure 2 shows that the death rates for the low-income countries is substantially greater than for the high and middle-income countries. On average, more than three times the number of people died per disaster in low-income countries than in high-income countries, with 332 deaths for the poorest countries versus 105 deaths on average in the richest countries [8].

COST OF NATURAL DISASTERS

Not only do natural disasters cause much destruction to the natural and built environment with loss of lives and associated physical, emotional and societal disruption, but they come with an economic impact as well. Disasters are very costly – they cause much damage, displace many people and require repairs and restorations to the built environment and community infrastructure, as well as the rebuilding of people's lives and livelihoods. Every year the National Oceanic and Atmospheric Administration of the USA (NOAA) compiles a list of natural disasters around the world that cost a billion dollars or more [9]. The NOAA reports that in 2017, the U.S. experienced a historic year of weather and climate disasters with a total of 16 separate billion-dollar disaster events including: three tropical cyclones, eight severe storms, two inland floods, a crop freeze, drought and wildfire (see Figure 3), with a cumulative cost of over \$300 billion [9].

Figure 3. Natural Disasters in the US in 2017 that cost more than \$1 billion each [9].

GEOPHYSICAL DISASTERS

Tsunamis [10]

The Indian Ocean tsunami of 2004 was a consequence of an undersea earthquake with a magnitude of 9.1 that struck the coast of the Indonesian island of Sumatra devastating coastal areas as far away as East Africa. Some locations reported that the waves had reached a height of 30 feet or more when they hit the shoreline [11]. This tsunami caused massive damage and resulted in more than 225,000 deaths across twelve nations. The lack of food, clean water, and medical treatment, combined with the enormous task faced by relief workers trying to get

supplies into some remote areas where roads had been destroyed or where civil war raged, added to the numbers of casualties. Long-term environmental damage was severe, with villages, tourist resorts, farmland, and fishing grounds demolished or inundated with salt water, debris, and bodies. Displacement and damage to infrastructure are important contributors to the human, social, and economic toll of tsunamis. The damage took a long time to repair and cost billions, but psychological scars remain.

The tsunami that hit Japan in 2011 was the consequence of an earthquake with a magnitude of 9.0 located some 80 miles east of the city of Sendai [12]. It was not as fatal and the Indian Ocean tsunami of 2004, because of the limited impact and lower population density, with an estimated 28,000 deaths (just over 10% of the toll in the 2004 tsunami). While there was much structural damage to buildings, the greatest concern was the damage to the Fukushima Daiichi nuclear power plant, which resulted in the release of ionizing radiation into the air, the soil and the water characterizing it as a Technological Disaster as well, with unexpected and cumulative consequences. The severity level of the nuclear emergency at the Fukushima Daiichi facility was estimated to be from 5 to 7 – the highest level on the scale created by the International Atomic Energy Agency – placing the Fukushima accident in the same category as the Chernobyl accident, which had occurred in the Soviet Union in 1986. The repair and recovery of the plant was expected to take about 10 years, but the fallout is expected to last decades. The impacts on humans physically, emotionally and socially are concerning with increase in mortality among vulnerable populations [13].

Earthquakes [14]

The impact on the built environment and on humans from earthquakes is related not only to the intensity, as measured on the Richter Scale, but also has as much to do with the location of the epicenter and its proximity to population centers, as well as the infrastructure of the built environment. We will examine earthquakes in 2 countries in the same year – approximately 1 month apart from each other that serve as a contrast of the consequences in the 2 countries.

Haiti 2010

On January 12, 2010, Haiti was hit by a magnitude of 7.0 earthquake centered about 15 miles southwest of the Haitian capital of Port-au-Prince with a sizable number of aftershocks [15]. As a result of the location close to the densely populated capital, as well as vulnerable architectural infrastructure, the devastation was great. Furthermore, being a poor country with limited governmental infrastructure, the country was ill-equipped to deal with such a disaster [16]. Buildings collapsed because of lack of building codes, killing or trapping their occupants. Attempts to deal with the disaster by local citizens and organizations, as well as international agencies, including the United Nations, were hampered in their attempts to rescue people who were trapped, and were limited in their ability to provide medical care, food and water because the roads were destroyed or blocked with debris, which further

compromised the already limited transportation services. In addition, the failure of the electric power system and loss of communication lines, seriously limited traditional communication services. As a result of this rather chaotic situation, aid was delayed, and more people suffered and died. On a positive note, the country's computer network was functional, and electronic media emerged as a useful mode for coordinating relief efforts and for connecting family members separated by the quake.

An estimated three million people were affected by the quake—nearly one-third of the country's total population, and an estimated 250,000 people died. Over one million people were left homeless in the immediate aftermath and had to live in tent camps with extremely limited resources. Due to major devastation and disruption of civil society, the physical and mental health needs for children were dire [17]. Infectious diseases were a major cause of morbidity and mortality in children as well traumatic injuries and malnutrition. Children also suffered abuse and violence with symptoms of posttraumatic stress disorder (PTSD), peritraumatic stress, depression, anxiety, and food insecurity [18]. Of particular concern was the situation of children who had lost their parents and were left vulnerable to abuse and human trafficking. Fortunately, many were adopted by families in other countries, particularly in the United States.

To add insult to injury there was an outbreak of cholera, which was apparently brought to Haiti by members of the UN Peacekeeping Force and, with the cramped and unhygienic living circumstances and lack of adequate healthcare, 283,362 cases of cholera had been reported to the national cholera surveillance system, including 152,816 hospitalizations and 4,856 deaths [19].

The sad reality of this disaster is that it was a massive earthquake that devastated one of the poorest countries in the world and, because of the lack of infrastructure at so many levels, even the best efforts of local and international organizations and agencies were unable to effectively manage the situation. This resulted in a high morbidity and mortality with infrastructural impacts that have residual consequences. At 5 years post-disaster, thousands of people remained displaced and to date, now 10 years later, the people of Haiti are still struggling to recover [20].

Chile 2010

One month after the earthquake in Haiti, on February 27, 2010, there was a magnitude-8.8 earthquake off the coast of south-central Chile, causing widespread damage on land and initiating a tsunami that devastated some coastal areas of the country [21]. Although this earthquake was of a much greater magnitude than the one in Haiti, and was associated with a tsunami, the epicenter was about 200 miles southwest of the city and so the impact on the city and its inhabitants was not as devastating. In addition, in stark contrast to the earthquake in Haiti, Chile had experienced previous earthquakes, which prompted the government to institute stringent building codes that significantly limited the damage to buildings. Furthermore, the infrastructure and financial resources of Chile were substantial enough to mobilize more than 10,000 troops to the devastated areas to direct recovery operations and maintain law and order. The Chilean government officials estimated that two million people

had been directly affected by the quake and that the earthquake and tsunami resulted in about 500 deaths, in contrast to the number of people affected and the deaths in Haiti [22].

Although the situation was far from perfect and the Chilean Government requested aid from the UN and the US, recovery efforts resulted in a relatively effective return close to previous functioning status by about the middle of 2014. Furthermore, precautions taken in the wake of the 2010 catastrophe were credited with saving lives during a magnitude-8.2 quake and tsunami that occurred in the northern part of Chile in April 2014 and in the September 2015 earthquake off the coast of Illapel. Not only did the people of Chile focus on the practical approach to disasters, they also examined the psychological impact and approaches to ameliorating associated emotional stresses [23].

METEOROLOGICAL DISASTERS

Tornadoes

Tornadoes are violently rotating columns of air extending from the base of a thunderstorm down to the ground and are capable of completely destroying well-made structures, uprooting trees, and hurling objects through the air like deadly missiles. They can occur anywhere, at any time of the day or year but most commonly in the Central Plains and the southeastern US. If there is warning of a tornado, it is advisable to seek shelter with attention focused on the safest place within home [24]. However, people living in mobile home are uniquely vulnerable. Although some mobile parks have shelters, this is not common. Because of the short time interval between the warning and the landfall, the effectiveness and functionality of local warning sirens and alert systems are paramount. However, these systems do not always reach everyone at risk, either because of inadequate design or malfunction, leaving residents at risk and vulnerable to the devastation the tornadoes wreak on their fragile homes, leaving them effectively homeless [25].

Heat Waves

Heat wave are periods of unusually hot weather that typically last two or more days with temperatures outside the historical averages for a given area. Over the past 5 decades, heat waves, like other natural disasters, have increased in frequency and duration. Typically, the elderly who are socially isolated and living in inner city tenements, which function as 'heat islands' [26], are at greatest risk and those with medical illnesses and taking multiple medications are even more vulnerable. Even brief daily exposure to air conditioning has been found to be effective [27], and public health practice is to establish programs to bring the elderly to air- conditioned malls or other such venues for daily opportunities to cool down [28].

Wildfires

Wildfires are any unplanned fires that burn in forests and other wildlands, such as shrub or grass communities. They can burn millions of acres of land at rapid speeds and can consume everything in their paths, and they are difficult to contain. Concerns about wildfires have increased dramatically with the sharp rise in number and severity of California wildfires (2017-19) and the dramatic events unfolding at this time of writing, in Australia (January 2020) [29]. Consequences result in burn injuries from fires, respiratory distress from the acute dramatic rises in particulate air pollutants as a result of the smoke, and the challenges in recovery for communities devastated by the fires. Vulnerable groups accordingly are low income, low resource populations who were forced to move ever further from high cost urban areas and ever closer to at-risk forests; firefighters, emergency responders, and others caught up within ever shifting flames and vulnerable to burn injuries; and individuals with pre-existing cardio-respiratory diseases such as asthma, COPD, and cardiovascular disease who are most heavily impacted by the acute rises in particulate air pollution. The CDC provides valuable information on how to prepare for and protect from wildfires [30]. However, given the unpredictable vagaries of huge forest fires, even well-to-do and very prosperous communities, such as those adjacent to Los Angeles, can also find themselves at risk, with sudden changes in wind and temperature superimposed on drought conditions. The consequences from the total annihilation of the built environment from wildfires in the losses for individuals and families are great, as are the impacts on the communities and society, financially and ecologically.

Hurricanes [31]

Hurricanes are considered the most violent storms on Earth and are called by other names, such as typhoons or cyclones, depending on where they occur (Figure 4) [32]. The scientific term for all these storms is *tropical cyclone*.

Figure 4. Illustrates the terminology of tropical cyclones depending on where they are located [32].

The classification of hurricanes depends on wind speed, which will determine the consequences on the natural and built environment and on human and animal life (see Table 1) [33].

Table 1. Hurricane categories with associated damage

• Category 1 – winds 74-95 mph - very dangerous winds will produce some damage – storm surge 4-5 feet • Category 2 – winds 96-110 mph - extremely dangerous winds will cause moderate damage– storm surge 6-8 feet • Category 3 – winds (major) 111-129 mph - extremely dangerous winds will cause extensive damage – storm surge 9-12 feet • Category 4 - winds (major) 130-156 mph - extremely dangerous winds will cause extreme damage – storm surge 13-18 feet • Category 5 – winds (major) 157 mph or higher - extremely dangerous winds will cause catastrophic damage – storm surge 19+ feet

According to the Stormfax Weather Almanac 1851-2017 there have been an average of 12 named storms per year with 6.5 per year designated as hurricanes and 2 per year that are classified as major hurricanes of categories 3-5 [34]. Of note is that in 2005, the year of Hurricane Katrina, there was a high of 28 storms, with 15 hurricanes and 7 major hurricanes. In 2017 with hurricanes Harvey, Irma and Maria there were 17 storms, 10 hurricanes and 6 major hurricanes (Figure 3).

Individuals living in flood zones and historically impacted coastal areas are obviously most vulnerable. Over the years, the national system of river levees, and the practices of sheltering and evacuation in hurricane affected coastal areas, has provided significant protection in the US, however, these systems have been coming under increasing stress in recent years, thus increasing vulnerability. At the same time, there have been additional increasing risks, which include:

- more frequent high-category hurricanes leading to greater damage and flooding, and overwhelming protective mechanisms (e.g., Hurricanes Katrina, Sandy, Maria, Harvey);
- inadequate insurance and recovery funds, leaving many with long-term vulnerabilities (e.g., Hurricane Maria in Puerto Rico);
- aging levee systems which in some cases are inadequate (e.g., Hurricane Katrina and New Orleans) or whose design is coming under increasing scrutiny because of concerns about effectiveness (e.g., Midwest and Mississippi floods, 2019), leaving increasing numbers of people at risk;
- the increasing impact of climate change.

Hurricane Katrina

With all the storms and hurricanes over the years, Hurricane Katrina stands out as the most devastating and deadliest hurricane since the Galveston hurricane of 1900, which killed

an estimated 6,000 to 12,000 people [35]. Hurricane Katrina is well recognized as both a natural and technological disaster and demonstrated graphically the triple threat burden: historic health disparities, persistent environmental health risks, and living in a disaster-prone area [36].

Katrina made landfall in southeast Louisiana on August 29, 2005, as a Category 3 hurricane and rapidly became a category 5 hurricane, with sustained winds up to 120 mph making it the third-strongest hurricane ever to affect the United States [37, 38]. The resulting storm surge produced waves that were almost three stories high along with 8 to 10 inches of rain that fell along the coast resulting in extensive flooding all along the U.S. Gulf Coast in the states of Mississippi and Louisiana. With much of New Orleans below sea level, the flooding was compounded by more than 50 breaks in levees and floodwalls which resulted in the flooding of 80% of the city. Neighborhoods were destroyed and reduced to scattered rubble. The flooding affected an estimated 77% of the population of Orleans Parish and nearly all the residents of St. Bernard Parish. To further compound matters, at least four Superfund sites in the New Orleans region were hit by the storm and the flooding also resulted in release of noxious chemicals including 575 reports of petroleum or hazardous chemicals spills that were widely distributed by the floodwaters. There were approximately 1,000 deaths from Katrina with 40% from drowning, 25% from injury and trauma and 11% from heart conditions [39].

The destruction of property and displacement of people as well as the disruption and necessary restoration of neighborhoods came at a significant human and financial cost. While the human cost is difficult to determine, the financial cost as estimated by NOAA was at \$161 billion – the highest of all hurricanes on record [40].

Although a disaster is indiscriminate, the poor and medically underserved bear an inequitable degree of the burden [41]. In Orleans Parish, the mortality rate among black Americans was 1.7 to 4 times higher than whites for all people 18 years old and older [39]. These statistics are not surprising in that thousands of low-income minority people of New Orleans, where 69% of the population is African American and 23% live below the poverty line, were living in substandard housing. These areas were totally inundated with the flood waters destroying the fragile buildings and drowning the residents who had not fled the area. Of the other vulnerable groups of people, those who were 75 years old or greater were significantly more likely to be storm victims [37-39].

There had been warnings of the impending storm urging residents of the threatened areas to evacuate to safer areas. The unfortunate reality was that many of the poorer residents of the city, particularly from the most vulnerable areas, did not respond to the warning. Several reasons are postulated. It is possible that some of the residents did not tune into the news or hear the warning because of lack of connection with media. Some may have heard the warning but did not give it credible consideration. Some have previously voiced suspicion and skepticism of the warning sources, displaying general governmental distrust or any source that may appear to be from government [42]. Others may not have had reliable sources of transportation or funds necessary to purchase transportation. Some may have been concerned about their potential loss of property or possessions. Finally, some may have been too old, too ill, or physically and mentally unable to take advantage of the opportunity to flee from a potential source of danger. Thus, the people who ultimately lost their lives, their livelihoods, their possessions, their loved ones, their health, their well-being and self-

sufficiency were those who were poor, with limited education, limited resources and limited social capital [43].

While more affluent and able citizens heeded the warnings and had sufficient presence of mind and practical resources to leave the threatened areas, thousands of those who remained were herded into the Superdome where they were destined to stay in crowded under-resourced conditions to weather the storm. First-hand reports of the conditions were harrowing with stories of lack of sufficient food, water or medical supplies, lack of sanitation resulting in garbage piling up, and lack of decorum devolving into a dystopian experience [44].

The aftermath for the survivors was dispiriting; with the destruction of homes, loss of possessions and loss of loved ones, they suffered consequences on their physical and mental health with resultant sense of despair and depression affecting children and adults alike. Furthermore, medical resources were limited because hospitals and clinics were also destroyed by the flood, thus taking years to reestablish their lives, their health, their communities, and their sense of well-being.

Another consequence of the widespread damage and destruction was a severe compromise of the public health system in the months after the storm, which, along with substandard living conditions, caused this increased mortality rate, particularly among socially vulnerable groups such as women, children, the elderly, and people with disabilities [38]. During the recovery phase there was a 47% increase in the mortality rate from January to June 2006 for the greater New Orleans area. The monthly mortality rate for this time period averaged 91.4 deaths per 100,000 persons, compared with a monthly average of 62.2 deaths per 100,000 for the years 2002–2004 [45].

Children shared many of the environmental and other ubiquitous hazards in New Orleans following the hurricane, such as widespread exposure to mold and heat, vectors, unsafe food, and poor shelter [46]. Additionally, there were many concerns that applied specifically to children, such as: the hurried mass transport of very sick neonates and children from New Orleans hospitals during the evacuation of the city; the closing of many pediatric practices in the face of the hurricane, many of which did not reopen; and the disruption of necessary pediatric practices such as newborn screening [47]. There were also some unique aspects to the mental health of children caused by the disruption and frenzied evacuation, the fragility of some of the shelters, the separation of thousands of children from their parents and caregivers, the shock of returning to destroyed or heavily damaged homes, and the limited mental health resources for returning or relocated children [48].

Thousands of Gulf Coast families displaced in 2005 by Hurricanes Katrina and Rita were victims of an unprecedented epidemic of chronic medical and mental health problems yet received little appropriate care at the time [49]. Even a year later, over half of the New Orleans population had not returned—perhaps as many as three hundred thousand people, many in FEMA-subsidized trailer parks and many in other parts of the country as climate refugees.

While many families who had fled the disaster returned to their original communities, a sizable number stayed in their new locations. They too needed to rebuild their lives and their livelihoods, settle into new school systems and to begin to belong to a community. After Hurricane Katrina, just over one-half of adults returned to the New Orleans metropolitan area, with only one-third returning to their original dwelling. Among the remainder, Texas was the leading location of displaced residents (18%), followed by other locations in Louisiana

(12%), other southern states (12%), and elsewhere in the United States (5%). Black adults were considerably more likely to be living elsewhere in Louisiana, in Texas, or other cities in the South [50, 51].

Hurricane Katrina made it evident that natural disasters occur in the same social, historical, and political environment in which disparities in health already exist (36,002042). Furthermore, the racial animosity revealed in a *Washington Post*/Kaiser Family Foundation/Harvard University poll of 680 evacuees, 93% of whom were African American, found that 68% believed the response would have been quicker for White and wealthier people and 61% said that the government does not care about “people like them”. These communities experienced social disparities in health before Katrina; their health status was linked to the toxic mix of poverty, poor housing, lack of economic opportunities, and the atmosphere of discrimination in which they lived [52].

The bottom line of the story of Hurricane Katrina and its impact, is that low income, minority people especially the elderly and young children, who live in disaster prone areas of poor neighborhoods, have existing health disparities, or are disproportionately affected by the disaster, are more severely affected by the disaster and have a greater difficulty in recovering from the disaster, if they ever do [36].

Hurricanes in the Caribbean

The vulnerability of the Caribbean islands to natural disasters can be seen in the example of the earthquake in Haiti, referred to earlier in this paper. The islands are small, generally poor and inhabited predominantly by people of African descent. Although some do have agricultural economies, they are heavily reliant on tourism for their main source of revenue. Being in the Caribbean, they are particularly vulnerable to hurricanes. In over 4 consecutive seasons, the Caribbean has experienced several Category 5 Atlantic hurricanes: Matthew (2016), Irma (2017), Maria (2017), Michael (2018) and Dorian (2019). During 2017 alone, 22 of the 29 Caribbean islands were affected by at least one storm, and multiple experienced extreme damage [53]. Furthermore, the devastation caused by the hurricanes is not only on the immediate destruction and death toll, but like the example with Katrina or like the earthquake in Haiti, it is long-term. The devastation of the islands’ infrastructure with their limited resources, can take years to rebuild. The inevitable stress affects the physical and mental health of the people and, with limited health care resources, can result in an increased morbidity and mortality [54].

These storms and their impact on the Caribbean islands further exacerbate the health and wealth divide, contributing to the cycle of health disparities. The irony of the situation is that the Caribbean islands have an economic base in agriculture and tourism, contributing a miniscule amount of greenhouse gases to the atmosphere, yet, they are in the line of fire from the hurricanes that are coming more frequently and fiercely as a result of the global climate changes that are caused by greenhouse gases from the richer industrialized countries [53]. A further example of disparities that play out in the political arena is that of Hurricane Maria that devastated the island of Puerto Rico in 2017. Here, the irony is that in the same year, the Hurricanes that hit the US mainland, Harvey in Texas and Irma in Florida, received substantial federal assistance from the US government through the Federal Emergency

Management Agency (FEMA), while Puerto Rico, effectively also part of the USA, did not receive commensurate assistance. This ultimately contributed significantly to the delayed implementation of emergency and rehabilitation services resulting in a further increase in morbidity and mortality [55].

VULNERABLE POPULATIONS

Vulnerable populations can be divided into two major categories: by geographical location, for example on a seismic fault line predisposing to an earthquake, in the equatorial region predisposing to hurricanes and tropical cyclones, or low-lying area predisposing to flooding; or by population characteristics, such as socioeconomic status, age, ethnicity, physical wellbeing, employment, family structure, and housing condition [7, 38 56]. Social vulnerability is a measure of both the sensitivity of a population to natural hazards and its ability to respond to and recover from the impacts of hazards. It is a multidimensional construct, not easily captured with a single variable. There is ample field-based evidence for understanding the characteristics of people and social groups that make them more sensitive to the effects of natural hazards and reduce their ability to adequately respond and recover [57]. Social vulnerability also refers to the resilience of communities when confronted by external stresses on human health, such as natural or human-caused disasters, or disease outbreaks. CDC's Social Vulnerability Index uses 15 US census variables at tract level to help local officials identify communities that may need support in preparing for hazards, or recovering from disaster (see Figure 5) [7, 38]. The CDC stresses that to mitigate the impact of disasters on at-risk populations, emergency managers must be aware of the social vulnerabilities within their community [58].

Figure 5. Social Vulnerability Index [7, 38].

DISASTER MANAGEMENT

As seen in the examples of natural disasters presented above, it becomes clear that acute and dramatic devastation to the built environment, the physical environment and the people who are affected, requires an immediate and dramatic response commensurate with the degree and nature of its impact. Furthermore, we need to be cognizant of the vulnerable populations and the long-term consequences. Then follows the steps in rebuilding and restoring a semblance of normality which takes much time. This is particularly the case for vulnerable communities who have limited resources to rebuild or return to their pre-disaster lifestyle. They require a significant level of assistance in recovering their physical and economic security as well as their emotional and social level of wellbeing. This calls for “a holistic community-driven and participatory approach beyond individual survival assistance.” [36]

While the damage cannot be undone, there are opportunities to rebuild the affected areas in creative ways that result in safer, healthier, and more resilient communities to better withstand future dramatic events [59]. The outcome of this process was described above in the situation of case of the earthquake in Chile, where the potential damage of the earthquake was mitigated by the building codes that had been instituted following previous earthquakes [21, 22]. Also, reflected in the reduced death toll from hurricanes [3].

Figure 6. Disaster management cycle [adapted from 60].

Figure 6 represents the elements of the Disaster Management Cycle demonstrating that the way in which we respond to disasters relies upon the crisis management, which informs risk management and disaster preparedness towards mitigation of the impact [60].

STORM DISASTER PREPAREDNESS

In their paper on the impact of hurricanes in the Caribbean, Schultz et al. make the following recommendations [61]:

6. *Communities need to prepare strategically* for the onslaught of stronger storms by revising building codes and redesigning neighborhoods to redress existing socioeconomic inequities in affordable, safe housing and putting in place systems to deal with power outages.
7. *Health care systems need to have emergency response strategies in place* in order to maintain access to lifesaving services and of life-sustaining treatments. This applies to trained personnel as well as hospital facilities.
8. *Enhanced warning systems*, and establishment of available and accessible resources for all citizens with special consideration to vulnerable populations.
9. *Active citizen participation in disaster preparedness and response* can make a big difference in saving lives but also in sharing the burden and working together fosters community cohesion and resilience.
10. *Collaborative conversations and planning process among various segments of society*, including but not limited to health professionals, climate scientists, population health scientists, government agencies and private organizations to advocate for policies that mitigate climate change and develop policies and practices that diminish population health risks and save lives.
11. *Elevate community resilience as an essential public health service* and consequently integrate community resilience measures as performance benchmarks of federal, state, and local health agencies.

Resilience

Resilience is a major factor in surviving a disaster as well as coping with the experiences emotionally, socially and economically in the intermediate aftermath and long-term.

The Composite of Post-Event Well-being (COPEWELL) is a module aiming to support community self-assessments to evaluate factors that influence resilience and incentivize the adoption of interventions that ultimately support National efforts of disaster preparedness, emergency response, and disaster recovery [62]. It insists that effective communication must exist in order for communities to function with resilience when faced with a disastrous event [63]. Because health care providers are inevitably at the frontlines of health management and patient communication during and after the disasters, the CDC has developed a public health training program entitled, “Crisis & Emergency Risk Communication” (CERC) [64]. This multidisciplinary curriculum offers in-person and online instruction for effective disaster communication before, during, and after events. It also offers guidance on handling sensitive topics with special populations and information specific to the type of disaster. It also focuses on the situation of children, who are particularly vulnerable to environmental health risks from disasters and require special attention to effectively address the physical, environmental and biological damage that disasters bring, as well as the emotional trauma that persists long after visible scars have faded.

CONCLUSION

The increasing frequency and severity of natural disasters in the last few decades that is most certainly related to global warming associated with climate change, if unchecked, will undoubtedly continue and become our new reality [4, 65]. The lessons learned over the past 20 years since the technological disaster that was the destruction of the World Trade Centers, and the natural disaster that was hurricane Katrina, have resulted in an ever-increasing set of strategies to anticipate and manage natural and technological disasters as they occur and reduce their impact on the environment and on human populations. Yet, the grave concern is that the frequency and severity of the natural disasters will continue to increase towards catastrophic proportions as we have witnessed in the recent fire in Australia [29]. Again, although a disaster is indiscriminate in whom it affects, the poor and medically underserved bear an inequitable burden [36, 39, 41, 43, 58]. The disastrous storms we have experienced, have not only demonstrated their capacity for destruction of property and impact on human lives, but they come at great cost and have also resulted in an aggravation of injustice with lasting consequences to human health and health disparities.

Our charge, therefore, requires efforts at many different levels involving many difference segments of our global society. We need to confront the imminent threat of global warming [4, 66] we need to continue to focus on the UN Sustainable Development Goals 2030 as a blueprint for action to improve the health of our world [67], all the while preparing for the next disaster wherever it may be and whatever its character [64]. Political leaders, health officials, preparedness and response professionals, and community organizations need to act now to develop a shared vision of optimal health for their community. A long-term plan for health and resilience should be a forethought, rather than an afterthought, when a disaster occurs [68, 69].

Chapter 334

BARRIERS AND OPPORTUNITIES FOR YOUNG CAREGIVERS TO PROVIDE NURTURING CARE IN LOW-INCOME COMMUNITIES OF PARAGUAY

ABSTRACT

The United Nations International Children's Fund (UNICEF), the World Bank, and World Health Organization (WHO) suggests a new roadmap for government action and for other programmers and service providers to implement policies and services that help parents and caregivers to provide nurturing care for their children. In Paraguay, despite existing Early Childhood Development (ECD) policies and programs, children, particularly those in poverty, continue to lag behind in many developmental indicators. Young children from low-income households are less likely to have adult members interact with them through stimulation activities, to attend early childhood education centers, or to have three or more books in the home. Furthermore, only 30% of babies are exclusively breastfed for six months, and with limited childcare options, often face greater protection risks from harm. This chapter explores the barriers and opportunities

* Corresponding Author's Email: jv2622@columbia.edu; jimevallejos@gmail.com.

that exist for caregivers to provide nurturing care to their children from pregnancy to age three years in low-income families of Paraguay. Based on a literature review, the mapping of existing ECD programs, and seven semi-structured key informant interviews, this paper analyses the current state of nurturing care in Paraguay. It uses the framework to advocate for the integration of interventions thorough a ‘whole child’ approach that takes into consideration the multidimensional nature of supports a child and his or her family need, and provides specific recommendations to break the cycle of health disparities with a focus on ECD for young children in Paraguay.

INTRODUCTION

The science of early childhood development (ECD) draws from multiple disciplines including behavioral and social sciences, neuroscience, biology, epigenetics, among others. Since the late 1990s, with ECD programs expanding across the globe, these disciplines have shaped a strong understanding of what constitutes healthy childhood development as well as the potential detrimental consequences for children and for society of failing to support the full development potential of every child [1]. At the same time, researchers have developed a solid understanding of what programs and support mechanisms best promote positive outcomes for children. We know today that the brain develops more rapidly in the first three years of life than at any other period in a child’s life, and that the architecture of the brain is the result of the interaction between our genetic makeup and the environment, especially our personal experiences early in life [1]. It is estimated that, during the critical period of the first three years, a child forms more than one million neuronal connections every second [1, 2]. During this rapidly growing period, many of the most basic functions that serve as a foundation for later learning and growth are developing. In order to grow, learn and thrive, children need responsive interactions with their main caregivers complemented by positive experiences and environments that help build a strong brain architecture. This translates into better opportunities for learning, improved health, and higher productivity [3]. An additional argument for supporting investment in the early years is evidence favoring that returns on investment for childhood development programs are greater in the early years. Allowing children to build a strong foundation from the very beginning is not only more economical in the long term, but it also promotes a preventive approach instead of an intervention approach, understanding that fixing negative outcomes from disorders of development result in more costly interventions [4].

Along with the growing knowledge of ECD science comes the understanding of factors that can disrupt healthy child development and put children at higher developmental risks. Given that children need nurturing relationships for healthy brain development, experiencing adverse environments and poor interactions puts at-risk children at a further disadvantage and reinforces health and developmental disparities. This may prevent children from developing the skills they need to cope with stress and develop resilience. When children grow up in challenging environments and do not have the support they need, toxic stress may develop as a defense mechanism [1]. Prolonged exposure to this type of stress can weaken the architecture of the developing brain [5]. The consequences of living in extreme poverty often exposes children to higher levels of toxic stress in early childhood and can have cumulative lifetime effects on learning, future earnings, and health [6].

Experiencing poverty early in life hence significantly contributes to health disparities in childhood as well as in the adult population [7]. This is because poverty has profound implications on key life circumstances, such as birth weight, infant mortality, language development, chronic illness, environmental exposure, nutrition, and injury [8]. These and other circumstances of poverty can also impact brain development given its association with a higher degree of stress connected with the need to obtain essential resources (food, housing, income) [9], and other challenges in the environment, such as exposure to violence [10].

Poverty adds further stress to the already challenging task of parenting, including the lack of access to parenting knowledge about the needs of the child for responsive and adequate caregiving and access to support networks to address these needs [3, 8]. The extent of a family's available resources in terms of financial, social and human capital, can influence a child's potential for reaching his or her optimal development [11]. In short, poverty can significantly reduce a caregiver's ability to support, protect, and promote young children's development. This study aims to answer the following question: *What are the barriers for young caregivers to provide nurturing care to their children in low-income communities in Paraguay?* It does so by analyzing the country's ECD landscape under a prominent framework to assess and organize action to promote Nurturing Care to inform future practice and opportunities for integration of programs and policies to achieve optimal development of children [12].

Nurturing Care

As described above, the evidence for investing in the early years has grown exponentially. However, even though increased investment has followed, this continues to be insufficient and insignificant portion of government expenditure in most Latin American countries [13]. In Paraguay, investment in young children ages 0-5 years represent less than 1% of the Gross Domestic Product (GDP), and less than 7% of total social spending. Furthermore, most of this funding corresponds to education expenses for children 3 years old and above (34%) and health (47%) [14].

An added challenge is that investment does not always translate into better development for children, especially when programs aim to operate at scale where maintaining quality becomes more challenging [15, 16]. New evidence is showing the importance of quality implementation in ECD, the fundamental role of multi-sectoral collaboration for its effective implementation, and the need for anchoring any efforts towards improving the development of children under the lens of the domains of the *nurturing care* framework [3].

Nurturing care is what children need for healthy development, and it can be understood as “the conditions created by public policies, programs and services ... (that) enable communities and caregivers to ensure children's good health and nutrition and protect them from threats. Nurturing care also means giving young children opportunities for early learning, through interactions that are responsive and emotionally supportive” [12]. Even though nurturing care can and must be facilitated and promoted at all levels and contexts (family, school, community, local, and national), it is important to emphasize that “the single most powerful context for nurturing care is the immediate home and care settings of young

children often provided by mothers, but also by fathers and other family members, as well as by child-care services” [3].

Figure 1. Nurturing care framework. Adapted from [12].

The Nurturing Care Framework (see Figure 1) developed by United Nations International Children's Fund (UNICEF), the World Bank, and World Health Organization (WHO); provide a roadmap for action which is unique in that it specifically targets the period from pregnancy to the age of three years as the most fundamental period for healthy brain development. The framework calls for a “whole-of-government” and “whole-of-society” approach, outlining principles, strategic actions and guidance for monitoring implementation of progress [12]. It is especially relevant for this research considering its age focus, as well as its emphasis on supporting caregivers with the right set of tools and knowledge that allow them to provide nurturing environments to their children. It reinforces the principle that, when provided with adequate and responsive nurturing care, children are more resilient to even the worst effects of adversity (such as extreme poverty). For this reason, guaranteeing nurturing care with healthy and responsive environments is one of the most important actions to help lower a child's stress level as it encourages his or her emotional and cognitive coping mechanisms [12].

The framework in Figure 1 describes the main domains of nurturing care: (a) good health; (b) adequate nutrition; (c) responsive caregiving; (d) security and safety; and (e) opportunities for early learning. It also shows the support system that needs to be in place to ensure that children receive nurturing care starting with caregivers' capabilities, empowered communities who own and defend child development, supportive services that guide caregivers through the challenging task of parenting in this critical period, and moves up to enabling policies that ensure all of the above and guarantee sustainability and continuity of services [12]. While the framework articulates the importance of integration across sectors, it also calls for the health sector to play a pivotal role as it is usually the main entry point for care and services during the early years.

Figure 2. Paraguay ECD indicators by wealth quintiles [17].

In addition to providing guiding principles for policy implementation, the framework for Nurturing Care identifies services and interventions that have proven successful to promote healthy childhood development worldwide under each of the domains presented above [3, 12]. While it is evident that different governmental and non-governmental institutions play different roles for the implementation and delivery of such services, this approach uses a whole child perspective allowing for integration of services based on a child's needs for optimal development rather than based on institutional capacities. This study is unique in that it assesses ECD in Paraguay using the Nurturing Care framework to make a case for integration of services at all levels and provide a series of recommendation for improving opportunities for caregivers in poor households to provide nurturing care to their children.

Early Childhood Development in Paraguay

Despite noticeable progress in health, nutrition and education enrollment in Paraguay, children's developmental outcomes vary significantly depending on where children grow up and their socio-economic status (see Figure 2). Children in the poorest areas are at greater risk for experiencing infant mortality or stunting and malnutrition. They are also much less likely to have adult members interact with them through stimulation activities (only 2 in every 10 children in the poorest households receive stimulation), to attend early childhood education centers, or to have three or more books in the house. Furthermore, they are more likely to be born to an adolescent mother and given that low-income families have limited childcare options children are often at greater risks of needing protection [17].

Paraguay presents an overall 81.9 score in UNICEF's Early Childhood Development Index (ECDI) [17, 18]. Figure 3 shows the distribution of ECDI scores by wealth quintiles in Paraguay. Even though most children are developmentally on track in terms of physical development (97,6%) and approaches to learning (95,8%), the development domains of literacy and numeracy, and socio-emotional development show greater variation and lags in development disproportionately affect children in the lowest wealth quintiles [17].

Figure 3. Distribution of ECDI scores in Paraguay by wealth quintiles [17].

In recent years, the increased interest in ECD has led to the development of a national plan for early childhood, the *Plan Nacional de Desarrollo Integral de la Primera Infancia* (PNDIPI) in 2011 and the launching of multiple ECD programs by public, private and civil society sectors. The PNDIPI was pivotal for introducing ECD in the national agenda and for complementing a legal and policy framework with clear action towards young children (see annex 1 for Paraguay's legal and programmatic ECD landscape). It set important targets for putting children at the center for intervention and called for a multi-disciplinary and collaborative approach to address young children's needs. One of its most important components, was the establishment of a national commission on early childhood, known as the *Comisión Nacional de Primera Infancia* (CONPI) as the key promoter agency for the implementation of the plan. This commission is formed by representatives of the Ministry of Health, the Ministry of Education and Science, and the Ministry of Childhood and Adolescence who rotate leadership positions. However, to date CONPI has played primarily a coordination function. As such, it is not an independent body and lacks the autonomy to demand implementation, influence policy and dictate fundamental aspects of the ECD agenda such as demanding funding allocation and monitoring and evaluation of programs.

The PNDPI will undergo an evaluation process at the end of 2019. Importantly, however, reports from key informant interviews, as well as a limited number of publications available on the subject, express important concerns in the translation of the plan from policy to implementation and sustainability [19].

OUR STUDY

A review of the literature was conducted to develop an understanding of the key concepts addressed in the research. The starting point was the recently published document *Nurturing care for early childhood development: A framework for helping children survive and thrive to*

transform health and human potential [11], which serves as the guiding framework for this research. The reference list of this document was reviewed and included to expand the research. In addition, Columbia University Library Database was searched using the terms “brain development,” “early childhood development,” and “nurturing care” “poverty and children health disparities,” “ECD policies in Latin America,” “Early Childhood Development in Paraguay” from 2000 through 2019.

Web searches on local websites of UNICEF Paraguay, Ministry of Childhood and Adolescence, Ministry of Education and Science, Ministry of Health as well as non-profit organizations was conducted to obtain program and policy information specific to Paraguay. Furthermore, the dataset from UNICEF’s Multiple Indicator Cluster Surveys conducted in 2016 was downloaded from UNICEF’s website and used to analyze and report ECD outcome indicators from Paraguay.

Finally, a series of in-person and remote key informant interviews with selected participants working in the ECD sector of Paraguay were conducted. The key informant interviews elicited stakeholder opinions on the relevance, effectiveness, efficiency, sustainability and impact of early childhood development programs in Paraguay, with special emphasis on opportunities and barriers for young caregivers to provide nurturing care. A detailed list of the institutions represented during the interviews as well as the guiding questions are included in annex 2. The names have not been included for confidentiality purposes. Data triangulation was achieved by interviewing a range of stakeholders at different levels from a variety of institutions and reviewing a wide range of documents.

Findings are organized under the main domains of the Nurturing Care framework with the intent of identifying the barriers for young caregivers to provide nurturing environments and highlight opportunities for integration and clear recommendations that can be adopted by policy makers and program implementers [12].

FINDINGS

Barriers for Caregivers to Provide Nurturing Care

This section assesses the main barriers to implementation of nurturing care from the perspective of practitioners and policy makers in Paraguay looking at both household and national level barriers. The end objective is to identify clear opportunities for aligning existing efforts and incorporating recommendations based on the Nurturing Care framework. For reference, findings from key informant interviews are highlighted in bold, and dimensions of the framework are marked in italics.

While it is important to understand the specific needs of children in the different domains of nurturing care, the first finding that became evident is how closely interrelated these domains are. This reinforces the idea that the inability of caregivers to fulfill needs within one domain, puts children at a greater risk in other domains as well [20]. For example, time and caregiver’s availability due to caregivers working 15-18 hours outside of the home was identified as a barrier for *responsive caregiving*. However, having caregivers on such a stressful schedule due to financial need is likely to also affect the caregivers’ capacity to provide *security and safety* as children are often left in someone else’s care because of the

work commitment of the primary caregiver. This may, at the same time, limit the caregivers' ability to seek timely healthcare and appropriate treatment when the child is ill, affecting the caregiver's ability to provide *good health*. What follows is an attempt to organize findings from the interviews under each domain, with the caveat that many of these barriers and challenges affect and relate to each other:

1.1. *Good health*: barriers to good health at the household level include,

- **Large percentage of teen pregnancies** among low-income caregivers put children at greater risk for low-birth weight and, consequently, poor development outcomes [21]. Every day two girls between 10 and 14 years old give birth in Paraguay [22]. These numbers are alarming given that a pregnancy in early adolescence is most often the result of sexual abuse [22]. In addition, the adolescent fertility rate is of 72 births for every 1,000 women ages 15 to 19 years, with adolescent mothers in this age range representing 20% of total births [17]. When disaggregated by region, language spoken at the home and years of study, the adolescent fertility rate goes up ranging from 84 to 164 births every 1,000 women ages 15 to 19 years, showing again a large disparity gap for adolescents in the poorest areas [17, 22].
- **Extreme climate events**: Extreme heat waves and periods of flooding are the largest environmental threats in Paraguay [23]. While flooding has been a challenge throughout history, the problem has exacerbated in recent years with more frequent floods and a larger number of families affected by these extreme weather events. Vulnerable populations are often displaced and face increased exposure to weather related diseases while experiencing additional sources of stress. Paraguay presents a vulnerability index classified as *extreme* and has been ranked as the 8th most vulnerable country to climate change Latin America and the most vulnerable in South America [24]. In 2019, over 49,637 families have been affected by flooding, with at least 11,144 families experiencing displacement [25]. In the context of these emergencies, ECD interventions are challenging to implement and national strategies for dealing with climate change, including Paraguay's, rarely include an intervention approach for the early years [26].
- **Lack of hygiene at the household level**: This barrier is reinforced by an overall lack of awareness and limited education in low income families as addressed in 1.3. below.

1.2. *Nutrition*: barriers to nutrition at the household level include,

- **Limited breastfeeding practices**: only 30% of children are exclusively breastfed until six months [17]. Mothers rarely receive sufficient guidance and support regarding the benefits and importance of breastfeeding for the developing child.
- **Malnutrition**: Paraguay achieved significant progress in reducing the rural-urban gap in nutrition since the mid 1990s until 2012 [27]. However, stunting levels still remain at 6% in children 0-5 years [17]. Today, in line with the global phenomenon, the country is beginning to co-exist with the challenges of eliminating undernutrition while increasingly having to pay attention to the **challenge of childhood obesity** with highly unbalanced diets. This is particularly worrying in vulnerable populations such as indigenous community that migrate to urban areas [28].

1.3. *Responsive caregiving*: barriers to responsive caregiving at the household level include,

- **Time** and caregivers' availability: As mentioned above, low-income caregivers who have to spend a significant portion of their days at work and leave their children under the care of others (often grandmothers or older children) face time constraints for spending quality time with their children.
- Intrusion of **mobile technology** into parental interactions was increasingly recognized as a challenge as parents tend to use technology to keep children entertained [29]. The framework recognizes the added premium that strong cognitive and social abilities that are development in the early years will continue to hold in our increasingly digital world. However, interventions must also stress the importance of human interactions with the main caregivers as the most fundamental factor to ensuring strong development in early childhood.
- **Culture**: Two important components were raised under culture. One is a culture of physical punishment which is addressed further in 1.5., and another commonly shared concern is the idea of **demonstrating affection as a symbol of vulnerability**. Children need love and affection. Boys and girls alike. An important finding at the national level highlights the need for gender sensitivity. Most of the concern was expressed around girls and their vulnerability to sexual abuse (also addressed in 1.5.); however, this finding also calls attention to possible risks regarding the way that children are socialized into different gender roles at a very early age and its possible negative effects on children's development [30]. Culture is also highly linked to opportunities for learning, for example, understanding the role and importance of play. This is addressed in the following point.

1.4. *Opportunities for early learning*: barriers to opportunities to early learning at the household level include,

- **Lack of awareness of the importance of play**: Caregivers often want to play with their children but there is a lack of awareness on the importance of early and responsive interactions, and the role of play in children's development. As it was put in one of the interviews "fathers wait until their child is old enough to play football, at that time, it can be late already." The value play and the implications of spending time playing with children, particularly in ages 0 to 3 years, have for the development of children is not internalized in most caregivers.
- **There is an existing notion that school, and learning, starts in pre-school**. There is a lack of awareness that learning begins at home and not when children enter the education system. In rural areas, children wait to be the same age to go to school together.
- **Location of early childhood education services**: Even if pre-school or early care services for young children are available, 3-year-old children cannot walk a kilometer to school as compared to school-age children.

1.5. *Security and safety*: barriers to safety and security at the household level.

- **Lack of basic income**: extreme poverty was identified as the main barrier to nurturing care in all interviews. Income poverty and extreme poverty affect 24.2% and 4.8% of the population respectively [31]. This barrier significantly affects the

ability of caregivers to provide nurturing care due to higher levels of stress, reduced levels of education, and lack of access to jobs as explained above.

- **Poor housing conditions and overcrowded households:** Paraguay has a household deficit of 50% with housing lacking both in terms of quantity and quality. The demand quantity is concentrated in urban areas due to large populations living in informal settlements whereas quality housing deficit in need of improvements and expansion is higher in rural areas [32]. The housing deficit is further exacerbated by the challenges resulting from flooding and an increase in the number of families and children living in informal, and often insecure, urban settlements.
- **Culture of punishment:** over 50% of children 1 to 14 years of age experience physical punishment or psychological aggression [17]. Families replicate what they know from their own experiences growing up' thus perpetuating the cycle of punishment.

1.6. *System barriers:* In addition to the barriers corresponding to the different domains within the Nurturing Care Framework, several barriers were identified at a systems and policy level. These relate to the implementation, monitoring and scaling up of national programs and policies. They include:

- The PNDIPI policy, which is in its last year of implementation, was identified as an opportunity and barrier at the same time. The policy has been questioned for its **lack of accountability**. While it was important for introducing new early childhood development programs, creating the CONPI, and suggest articulation across government actors, there is no clear evaluation or accountability mechanisms in place to understand how successful the plan has been in advancing and improving ECD.
- More importantly, there is no evidence that this plan **has translated into an integrated approach to child development**. In spite specific language in the plan advocating for interinstitutional collaboration, programs across ministries and institutions have mostly continued to work and develop in silos. Efforts to integrate operate primarily at a pilot stage. Furthermore, programs are often centralized at the ministerial level, leaving little capacity and discretion for implementation at the local level.
- Another important barrier is **institutional weakness**. This is expressed both in **limited multi-sector coordination and implementation** as well as in the limited transition of learning and progress from one administration to the next. While a right-based approach and a multi-sectorial approach is often discussed, programs in the field show little connection to each other.
- Finally, the Nurturing Care framework highlights the importance of funding that is "sustainable, equitably distributed, efficient and flexible" [11]. The last identified barrier to nurturing care is the **sustainability of the current ECD policy**. Financing of ECD occurs primarily through projects, multilateral cooperation, and yearly allocations rather than being embedded as part of the regular national budget.

Parents and other caregivers are the main force and resources for early childhood development in the first three years of life. For this reason, equipping them with the knowledge, capabilities and resources to provide nurturing care for their children in these five domains is essential for ensuring that they reach their full potential. These findings shed light

on the need to strengthen awareness raising services and streamlining information for caregivers in low-income families. Raising awareness is an important way of developing accountability mechanisms so that, in turn, government can become more efficient. Caregivers who know that providing nurturing environments for their children is a clear pathway towards breaking the cycle will be more likely to demand and use ECD services (see Figure 4).

Figure 4. Using the nurturing care framework to break the cycle of health disparities [12].

Opportunities for Caregivers to Provide Nurturing Care

While there are many barriers at the family, community and policy level to promote nurturing care in Paraguay, the literature review and interviews also revealed many opportunities to strengthen nurturing care at all these levels. Using the Nurturing Care Framework to organize and prioritize actions provides an opportunity in and of itself, but additional opportunities were identified and are important to take advantage of the momentum.

In 2018, the government of Paraguay in partnership with the Interamerican Development Bank and UNICEF launched two important initiatives. First, a new program, *Modelo de Atención Integral del Desarrollo Infantil Temprano (MAIDIT)*. The program aims to deliver ECD services through a model based on the public health system. It incorporates important components included as key practices in the Nurturing Care framework such as the

arrangement of programs and policies under a continuum of care with universal, targeted, and intensive services based on individual families' needs [12]. Second, the government of Paraguay launched the *Sistema Nacional de Protección Social ¡Vamos!* (SPS), a national social protection system as its primary platform for organizing its social policy at the end of 2018. The SPS organizes public action by lifecycle with a strong emphasis on early childhood. Both of these platforms present a unique opportunity for this study. Using Nurturing Care can provide further guidance for implementation of the MAIDIT program as it continues to roll out in 10 regions of Paraguay in the next few years [33] and for the SPS as it is rolled out nationally [34]. The PNDIPI and its upcoming evaluation was also highlighted as an opportunity given that it has provided extensive training for the early childhood workforce and put the CONPI in place. While there is much room for improvement, these mechanisms are very adaptable to the Nurturing Care Framework. Finally, it was largely recognized that in the South American region there are examples of best practices related to successful ECD policies that have been widely studied such as national ECD plans of Chile (Chile Crece Contigo), Colombia (De Cero a Siempre) and Uruguay (Uruguay Crece Contigo) that have been successful in improving child development outcomes indicators with a special emphasis on vulnerable populations (See Annex 3). An analysis of best practices of the region and exploring potential partnerships for adaptation and replication provide a unique opportunity for Paraguay to strengthen its current policies and programs.

DISCUSSION

This review presents a comprehensive analysis of the barriers and opportunities for parents and caregivers in Paraguay to provide nurturing care to their children in the first three years of life. It uses key findings from stakeholders' interviews combined with a review of the literature to highlight important gaps in guaranteeing the optimal development of children during this critical period. Below, I present key recommendations that emerged from the research under the five strategic actions recommended for governments in the framework for Nurturing Care [11]:

- 1) Focus on families and their communities:
 - The need to increase the knowledge and awareness of caregivers as well as their capabilities through providing timely information and adequate support systems for everyone must continue to be the primary vision for improving and ensuring the development of services for children in the early years, particularly for the most vulnerable populations.
 - Participatory processes for increased community involvement can bring new ideas not only for increasing awareness on nurturing care but for finding new practices and new ways of engaging in the way we care about children.
- 2) Lead and invest: Take into account regional examples of ECD laws and programs that guarantee long term financing and facilitate the integration of services across sectors. The Social Protection System is an important first step, but quality implementation at scale is key.

- 3) **Strengthen services:** This analysis identifies key barriers at the family, community and system's level. Organizing them under Nurturing Care provides a strong case for the need of improving efforts towards the integration of services as well as the introduction of new tools and mechanisms to facilitate such process. Global experiences show that interinstitutional ECD commissions, such as the CONPI, can play a key part of the coordination for the integration of services. Looking at regional examples can further inform how to improve the implementation capacity of this important unit and support the definition of a strong management model that guarantees access to services through vertical and horizontal coordination across governmental ministries, particularly for policy efforts such as the SPS.
- 4) **Monitor progress:** Integration needs to happen not only at the program level, but also in terms of sharing information around quality monitoring. Finding creative ways to make families accountable and increase their demand for services is an important step in improving the effectiveness of programs.
- 5) **Use data and innovate:** It is important to determine ways in which the data that is collected today at the family level can be used to inform actual needs and promote an ecosystem to nurture innovative solutions from different sectors. Furthermore, the integration of data information systems is an important step in efforts of intersectoral collaboration.

Expanding these lines of actions and taking into account the insights from this study can help overcome the barriers to nurturing care and break the cycle of health and developmental disparities for low-income children in Paraguay as it provides a roadmap for improving the current ECD landscape and transition into a holistic approach with caregivers and children at the center of any intervention (see Figure 4).

CONCLUSION

Placing emphasis on parents and caregivers' capabilities to provide nurturing environments for their children is fundamental for their optimal development. Paraguay has made good progress to establish policies and programs that promote ECD, however, its most vulnerable population continue to lag behind in many indicators of early childhood development. The inability to ensure optimal development of children has negative and long term social and economic implications for the country. For this reason, it is fundamental that current increasing interest in ECD and existing policies be translated into effective and high-quality implementation. The Nurturing Care Framework provides a roadmap to organize public action with a strong emphasis on developing and empowering parents and caregivers' skills and capabilities.

ACKNOWLEDGMENTS

A special thank you to Dras Cassie Landers and Renata Schiavo for their guidance, support and encouragement for the research in this topic and in general for encouraging me in

the pursuit of a career in this fascinating field. I also recognize the invaluable support and guidance of *Break the Cycle 14* faculty, mentors, and fellows. This work was conducted in honor and memory of Maren Castro Villagrana Jakobsmeier, SIPA MPA '18, a student dedicated to making the world a better place for children.

Chapter 335

THE DEVELOPMENT OF A PRENATAL CARE HEALTH LITERACY INSTRUMENT FOR AMERICAN INDIAN MOTHERS

Jordyn A. Gunville^{1,2,3,*} and Jessica A. Williams^{1,3}, PhD

³Department of Population Health, University of Kansas Medical Center,
Kansas City, Kansas, USA

ABSTRACT

American Indian (AI) women are nearly four times as likely as white women to experienced delayed prenatal care until the third trimester. Additionally, AI are the only racial/ethnic group that has not had a decline in infant mortality between 2005 and 2014. While these inequities are apparent, little is known about health literacy among AI women of childbearing age. Existing health literacy instruments do not take the cultural context surrounding the prenatal period into account. Method: After a comprehensive review of the literature of health literacy tools and questionnaires, a measure of prenatal care health literacy for AI mothers was developed with four domains. Measure development was iterative. Cognitive interviews, a standard technique to assist validation, were used to verify the face validity of the instrument and to check understanding in the population of interest. Results: The initial instrument had 60 questions. Iterative review by experts in population health and AI health disparity research eliminated 30 duplicative questions. Cognitive interviews were conducted with AI researchers and community members, after which 5 more questions were eliminated. These interviews also help establish the validity of the tool, understanding of the questions, and suggestions for formatting of the instruments. The final instrument consists of 25 questions. Discussion: Health literacy is the ability to obtain, process, and understand health information to make knowledgeable health decisions. There is little information on health literacy specific to prenatal care and infant health among AI. This instrument was developed specifically for this marginalized population.

INTRODUCTION

American Indian infants are 2.5 times more likely to die before their first birthday than non-Hispanic White infants [1-4]. While trends in maternal and infant health have been improving overall, American Indians are the only racial/ethnic group that did *not* have a decline in infant mortality between 2005 and 2014 [5]. High American Indian infant mortality rates persist, despite national, tribal, and community efforts to eliminate these disparities. The American Indian infant mortality rate is 9.4 per 1,000 live births compared with a non-Hispanic White infant mortality rate of 4.9 per 1,000 live births [1]. The leading causes of death for American Indian infants include congenital malformations, low birth weight, sudden infant death syndrome, and unintentional injuries [4, 6]. These high rates can be attributed to confounding factors of complex interactions of behavioral, social, genetic, environmental, geographic location, economic, and health care access [4, 7, 8].

The geographic isolation of American Indian reservations impacts the quality of life for the population, due to limited access to resources and services [8]. The American Indian population is additionally impacted by harsh environmental conditions, such as uncontrollable seasonal weather, poor road conditions, and inadequate housing [9]. American Indians living on reservations, whether in rural and urban areas, tend to have housing shortages, one aspect that contributes to having multiple families in one household, and poverty is also a continuing problem [10, 11].

American Indian mothers living on a reservation have additional barriers to medical care including limited insurance outside of the Indian Health Service (IHS) and limited access to transportation [12]. Some reservation IHS facilities do not have the capacity to deliver infants, so if a complication arises, a pregnant mother may need to travel 2-4 hours from the reservation to deliver the infant at a better equipped hospital. Often, continuity of care is lost when entering a new health system [8].

The rate of participation for American Indian/Alaska Native women in prenatal care is significantly lower (67%) than all other races in the US (81%), at least among those women using IHS [5]. In 2014, American Indian/Alaska Native mothers were 2.5 times as likely to receive late or no prenatal care as compared to non-Hispanic White mothers [13]. Prenatal care rates among American Indian women who do not use IHS are unknown—another serious gap in our understanding of this complex disparity. It is important to note that the mother may start prenatal care in an IHS clinic and at the time of the delivery must go to an outside health system. This transfer to a facility outside IHS is conflicting and complicated because of the universal coverage the mother gets within the IHS health system. IHS is a health system rather than an insurance plan and federally recognized enrolled tribal members do not pay premiums or co-pays. Non-IHS providers may be paid by IHS for care given to American Indians enrolled in a federally recognized tribe—making some care appear like traditional health insurance. IHS is budgeted on a global level, meaning that all care delivered by IHS and paid for by IHS must fall within a pre-set budget that is approved annually by Congress. This is unlike most of the rest of the health system in the US, which requires insurance with patients paying premiums and copays [14]. When women go outside the IHS system to receive care, their care is very difficult to track, especially if it is not eventually paid for by IHS.

Figure 2. Conceptual model.

Existing studies suggest that good health literacy among pregnant women is associated with better pregnancy outcomes [15-17]. While health literacy is, in some sense, a universal concept, a culturally tailored measure is essential for American Indians given their barriers to care, historical trauma, differing birth practices, and cultural roles [18-20]. The purpose of this study was to create a prenatal care health literacy measure specific to American Indian women to better understand literacy around prenatal care to improve birth outcomes and decrease infant mortality rates. Based on searches of PubMed, we are unaware of existing recent research on prenatal care health literacy among American Indian women. We expect that a Parental Care Health Literacy Instrument for American Indian mothers will help to break the cycle (see Figure 1) of high infant mortality by informing health care providers on providing impactful educational and clinical recommendation that are relative to the American Indian population.

OUR STUDY

The development of the measure began with an assessment of existing health literacy measurement tools. A search in PubMed, Cumulative Index of Nursing and Allied Health Literature (CINAHL) and ScienceDirect was conducted to compile a list of existing health literacy tools. Content coverage and validity information were compiled for the existing tools. Additionally, educational materials that are handed out to pregnant patients from an IHS clinic located near a local university was collected. The additional information was used to further check language and content areas that are important for health education related to pregnancy. After deciding on four topic domains including: awareness (care, warning signs, symptoms), screening (when, where/how, cost), mortality (rates and ranks), and risk

(activities that increase and decrease risk), questions for each domain were extracted from existing instruments to create a draft.

The draft instrument was then reviewed by three American Indian health disparity researchers and one population health expert for relevance, duplication, and content coverage for each domain. After review, certain questions were rewritten for relevance to the American Indian population.

Next, an assessment of the instrument was conducted through cognitive interviewing. Cognitive interviewing is a psychologically oriented method for empirically studying the ways in which individuals mentally process and respond to survey questionnaires [21]. Cognitive interviews can be conducted for the general purpose of enhancing the understanding of how respondents carry out the task of answering survey questions. For this study cognitive interviews were used as a pretesting question and determining how they should be modified making the instrument more understandable or otherwise easier to answer.

The cognitive interviews were completed by two American Indian community members and three American Indian health disparity researchers. None of the five individuals interviewed were involved in the original draft of the instrument.

During the interview one of the study authors (JG) asked the participants to go through each question and talk about what they thought of the questions and how they processed and understood the questions. Cognitive interviews were completed to ensure that the questions had face validity and that understanding was similar across likely respondents.

FINDINGS

Two major scales measuring health literacy in the context of pregnancy were identified in the literature from the literature search described above. The first scale is a psychometrically validated measure of a woman's preferences about a future pregnancy and childbearing (Desire to Avoid Pregnancy-DAP) [22]. The 14 items fit a unidimensional model, with a separation reliability of 0.90 (Cronbach's α : 0.95). The scale met established criteria for internal validity, including appropriately covering the ranges of women's preferences and correspondence between each item's response categories and overall scale scores. There was no important differential item functioning by key sociodemographic characteristics, garnering evidence for external validity [22]. The second scale, the Parental Understanding of Infant Health Information: Health Literacy, Numeracy, and the Parental Health Literacy Activities Test (PHLAT), which is used to assess parental health literacy and numeracy skills in understanding instructions for caring for young children [23]. During the validation of this scale, the authors found that many parents do not understand common health information required to care for their infants. The PHLAT long form and PHLAT-10 short form have good reliability and validity and may be useful tools for identifying parents who need better communication of health-related instructions [23].

After reviewing the two instruments just discussed, the authors created the original draft instrument to measure prenatal health literacy among American Indian women; it was made up of 60 questions. After review by experts in American Indian health disparity, many questions were eliminated because they were either duplicative or misleading, creating a draft long form of 30 questions. The instrument has four domains including: risk (ways to increase

and decrease risk), incidence and mortality (rates and ranks), awareness (care, warning signs, symptoms), and screening (when, where/how, cost). The four domains were chosen based on health outcomes and risk factors among this marginalized population and were agreed upon jointly by three American Indian health disparity researchers who work at the Center for American Indian Community Health at the University of Kansas Medical Center and one population health expert from the Department of Population Health at the University of Kansas Medical Center (JW).

Current health care related readability formulas were used to ensure the understanding of written information in clinical and health care settings [24]. We used two readability formulas, Simple Measure of Gobbledygook (SMOG) Readability formula and FRY readability formula named after developer Edward Fry. The SMOG Readability Formula is a simple method you can use to determine the reading level of your written materials. The FRY graph readability formula is used to determine the interpretation of graphics and numbers. The FRY formula is often used to provide a common standard by which the readability of documents can be measured. The instrument also includes aspects of prose (reading and writing), document (understanding and being able to fill out forms or charts/graphs), and quantitative (math, understanding numbers) literacy into the instrument; ensuring holistic representation of health literacy [25].

Each cognitive interview was around 30 to 45 minutes long and was conducted in-person. The interviewees read each question out loud, after reading the question they described their overall perception of the question including difficulty and readability. Through this interview and feedback, five additional questions were eliminated from the 30-question long form, making the final form 25 questions (see Figure 2).

Modifications of the instruments format was made based off the feedback from the cognitive interviews. If a question had fill in the blank questions, we put a number before the blank spot, making the longer fill-in-the-blank passages easier to follow.

<i>Risk</i>	
	According to the Centers for Disease Control and Prevention, birth defect occurs in the first 3 (1) _____ of pregnancy, when the organs of the baby are forming. However, some birth defects occur later in pregnancy. During the last (2) _____ months of pregnancy, the tissues and organs (3) _____ growing and developing.
	Alcohol in the mother's blood passes to the baby through the (4) _____. Drinking alcohol during pregnancy can cause miscarriage, stillbirth, and a range of lifelong physical, behavioral, and intellectual disabilities. These disabilities are known as (5) _____.
	Toxoplasmosis is a common (6) _____ caused by a parasite that, when contracted by a pregnant woman, can pose serious risks to her unborn baby. To avoid, it is recommended that you do not empty cat litter from outdoor cats, wear gloves when working in the garden, do not eat undercooked (7) _____ and wash produce before consumption.
(8)	Breastfeeding has been shown to decrease the risk of breast cancer.
(9)	Having your child at an early age (under age 35) has been shown to increase the risk of birth defects.
(10)	Smoking is also associated with lower IQ, higher miscarriage rate, higher risk of infant death at term and sudden infant death syndrome (SIDS).
(11)	A miscarriage is often caused by an abnormality with the pregnancy and a result of women's activities or stresses.
(12)	Smoking affects pregnant women by increasing risk for things such as preterm delivery, stillbirth, low birth weight, and _____.
(13)	Nasal congestion and nose bleeds are common throughout pregnancy. They are caused by _____.

Figure 2. (Continued).

Incidence and Mortality															
Use the graph below to answer questions 14-15.															
Infant Mortality Rates by Race and Ethnicity, 2016  <table border="1"> <thead> <tr> <th>Race and Ethnicity</th> <th>Rate per 1,000 Live Births</th> </tr> </thead> <tbody> <tr> <td>Non-Hispanic Black</td> <td>11.8</td> </tr> <tr> <td>American Indian/Alaska Native</td> <td>9.4</td> </tr> <tr> <td>Native Hawaiian or other Pacific Islander</td> <td>7.4</td> </tr> <tr> <td>Hispanic</td> <td>5.0</td> </tr> <tr> <td>Non-Hispanic White</td> <td>4.9</td> </tr> <tr> <td>Asian</td> <td>3.6</td> </tr> </tbody> </table>		Race and Ethnicity	Rate per 1,000 Live Births	Non-Hispanic Black	11.8	American Indian/Alaska Native	9.4	Native Hawaiian or other Pacific Islander	7.4	Hispanic	5.0	Non-Hispanic White	4.9	Asian	3.6
Race and Ethnicity	Rate per 1,000 Live Births														
Non-Hispanic Black	11.8														
American Indian/Alaska Native	9.4														
Native Hawaiian or other Pacific Islander	7.4														
Hispanic	5.0														
Non-Hispanic White	4.9														
Asian	3.6														
Incidence and Mortality, continued.															
(14)	In 2016, the infant mortality rate for American Indian/Alaska Natives was ____ per 1,000 live births.														
(15)	In 2016, the infant mortality rate was the highest for _____.														
Awareness															
(16)	Signs of miscarriage are usually vaginal bleeding and cramping.														
(17)	When you are pregnant, you need about 300 calories more a day than you usually eat.														
(18)	During pregnancy, you should continue routine dental care including cleanings, extractions, root canal, radiographs, and fillings.														
(19)	The increase hormones of pregnancy make the gums more susceptible to plaque buildup and bacteria causing pregnancy _____.														
Screening															
(20)	A preconception care visit can help women take steps toward a healthy pregnancy before they even get pregnant.														
Prenatal care is the regular visits you will have with your physician during your pregnancy. In the beginning of your pregnancy, you will be seen monthly if everything is progressing well. Starting around week 28, your visits will change to every (21) _____, and then every (22) _____ the last month.															
Taking folic acid daily reduces the risk for neural tube defects by (23) _____. Most prenatal vitamins contain the recommended (24) _____ of folic acid as well as other vitamins that pregnant women and their developing fetus need.															
(25)	It is important to notify your doctor if your baby has not moved ten times in two hours, you have not felt the baby move all day (12 hours) or you notice a significant change in your baby's activity.														

Figure 2. Final questions for prenatal health literacy instrument.

Similarly, further refinement of the instrument was made based on feedback and results from the cognitive interviews, changing wording where appropriate and arranging the instrument in chronological order from preconception to birth. The first section contains 13 questions that gauge knowledge of health, prevention, and risk factors during pregnancy. The second section contains a graph showing infant mortality across race and ethnicity, two questions are based on the graph. The purpose of this section is to understand how the participants interpret information from graphics. The third section, warning signs included four true and false question asking about warning signs during pregnancy. The fourth section includes six questions in the form of multiple choice, reading passages, and true and false questions focusing on development, health, and screening points for the fetus.

DISCUSSION

Infant mortality among American Indians is higher than among whites and is not dropping at the rate seen in other populations [1-4]. While the complex interactions between risk factors such as poverty, housing, and healthcare access are central to reducing infant mortality, adequate prenatal care may address some risk factors directly [4, 9, 18]. American Indian infants are nearly 4 times as likely as non-Hispanic White infants to have mothers who only received prenatal care in the third trimester, or not at all [26]. Prenatal care and health screenings can improve health outcomes for both American Indian mothers and their children by providing health education and knowledge, informing behavior change, and increasing the awareness of necessary interventions [20, 27, 28].

The cycle that creates these poor outcomes can be broken. There are several intervention points. However, due to cultural differences, geographic barriers to access, differences in health policies, and legacy of discrimination, a highly interconnected approach is needed to address the high infant mortality rates among American Indians. [20, 27, 28]. Prenatal health literacy among American Indian mothers has not been measured. We developed a measure of health literacy that is specific to this population to support further efforts in the area.

This measure of prenatal health literacy is a beginning to understanding the needs and desires of this important population. Improving outcomes will only be impactful if the interventions and approaches address the literacy of the population as well as the unique factors affecting outcomes. The Prenatal Care Health Literacy Instrument breaks the cycle of childhood health disparity by improving birth outcomes at the start of pregnancy. This instrument is a tool used to assess the literacy level of the mother to enable her to get the care and information she needs during and after their pregnancy. This instrument also breaks the cycle by providing detail about health literacy in this population.

This instrument is different than other measures both in content and form. It was developed for a specific marginalized population, American Indians. American Indians have their own sovereignty, because of this, policy within different tribal nations and communities may be different than the surrounding areas. Medical training often neglects to cover this special population. Without an understanding of the cultural and contemporary life of tribal nations, as well as their traditional health practices, it is difficult for providers to form bonds with American Indian patients and have barrier-free communication. Future work will use this instrument to understand prenatal care health literacy of American Indian mothers. By understanding the health literacy of prenatal care, the gap can be closed through informing providers on what type of health information is most beneficial for American Indians mother during a prenatal care visit. This may also help bridge the gap between patients and providers, which will 'break the cycle' and improving the care for American Indian mother and reduce poor birth outcomes.

CONCLUSION

Although trends in maternal and infant health have been improving overall, American Indians are the only racial/ethnic group that did not have a decline in infant mortality [5]. The high rates of infant mortality are possibly related to poor health literacy and lack of access.

The development of this prenatal care health literacy instrument for American Indian mothers is a tool to evaluate prenatal care health literacy. We hope that this instrument will be used to assess health literacy so that it can be improved. Increased health literacy has the potential to improve pregnancy and birth outcomes. The next steps include, pilot research of this instrument will be conducted in American Indian communities throughout the US, both on reservations and in rural areas to assess both validity and feasibility.

ABSTRACT

Adverse childhood experiences (ACEs) were defined in the landmark 1998 CDC/Kaiser Permanente Study as traumatic experiences during childhood. These include any form of abuse, neglect, or household dysfunction, such as parental divorce, intra-parental violence, parental addiction, incarceration, and mental illness. ACEs have been shown to substantially contribute to serious health problems in later life, such as mental illness, addictive behaviors, obesity, cardiovascular disease, and other chronic conditions. Numerous epidemiologic studies have demonstrated that exposure to an increased number of ACEs is associated with poorer health outcomes. While ACEs affect all socioeconomic classes, there is a higher prevalence among low-income populations. Interventions that support parenting and address family, social, and economic stressors have been shown to mitigate the impact of ACEs on future health. We sought to develop a process for addressing ACEs in a pediatric primary care office with an existing integrated Behavioral Health and Resource Team. We first assessed baseline knowledge

* Corresponding Author's Email: QUIZHPI@mail.etsu.edu.

and perceptions of ACEs among a sample of our clinic providers and local parents/caregivers. Next, we developed, and pilot tested a screening, brief intervention, and referral protocol to provide parenting resources and other supportive measures that would mitigate ACEs and promote resilience in both the parents/caregivers and children. Finally, we surveyed parents/caregivers of patients to obtain their feedback on feasibility, acceptability, and appropriateness of ACEs screening. Our long-term goals are to identify effective feasible pediatric primary care approaches to addressing trauma, promoting resiliency, and breaking the cycle of trauma and health disparities.

INTRODUCTION

The term *Adverse Childhood Experiences* (ACEs) is used to describe a wide range of traumas experienced during childhood including abuse, neglect, and other stressors. The 1998 study by the Centers for Disease Control (CDC) and Kaiser Permanente assessed 10 types of ACEs: five personal — physical abuse, verbal abuse, sexual abuse, physical neglect, and emotional neglect; and five related to dysfunction in other family members: parent alcohol abuse, domestic violence against the mother, parental incarceration, parental mental illness, or the loss of a parent through divorce, death, or abandonment [1]. In the seminal study published in 1998, data was collected between 1995-1997 from 17,000 Kaiser members who completed surveys on their childhood experiences and current health status and behaviors [2]. This study assessed the association between the 10 ACEs and adult health outcomes including mental health (depression, suicidality), physical health (heart disease, cancer, chronic lung disease, skeletal fractures, liver disease, obesity), and health-related behaviors (alcoholism, drug abuse, smoking, high numbers of sexual partners) [2]. Prior to that survey, there had been no studied association connecting early childhood adverse experiences and adult medical problems and behaviors.

In the 1998 study, the authors aggregated the reported ACEs (each counting as one point) into a total ACE score. For example, a respondent who reported experiencing physical abuse, witnessing a parent being physically abused, losing a parent to incarceration, and experiencing life with a parent who suffered from mental illness during childhood would have an ACEs score of 4. The study concluded that individuals with higher ACE scores had a higher risk of developing the above listed poor health outcomes as adults. Persons who had experienced four or more categories of childhood exposure, compared to those who had experienced none, had 4- to 12-fold increased health risks for alcoholism, drug abuse, depression, and suicide attempt; a 2- to 4-fold increase in smoking, poor self-rated health, ≥ 50 sexual intercourse partners, and sexually transmitted disease; and a 1.4- to 1.6-fold increase in physical inactivity and severe obesity [2]. Additionally, adults with the highest number of ACEs had a life expectancy 20 years less than those with fewer ACEs [1].

Subsequent to the CDC/Kaiser study, there have been many other studies examining the relationship between ACEs and adult health. A meta-analysis of population-based studies published through 2016 included 37 studies with 23,719 participants [3]. The study found strong positive associations between an ACE score of 4+ and all measured negative health outcomes, such as overweight, diabetes, problematic drug use, violence, alcohol abuse, sexual risk taking, and mental illness. Furthermore, other studies have shown that ACEs were positively associated with poor health outcomes in adolescents, such as increased rates of

early sexual debut, teen pregnancy, self-harm, suicidal ideation, and suicide attempts [4]. Furthermore, studies have shown that women who report greater exposure to ACEs have a greater risk of experiencing very early sexual initiation and increased potential exposure to Human Immunodeficiency Virus and Sexually Transmitted Illnesses' [5].

Current research is starting to show that ACEs create a pathological condition called 'toxic stress' that can play a powerful role in disrupting the architecture of the developing brain, thereby negatively influencing behavioral, educational, economic, and health outcomes [6]. Childhood trauma and toxic stress adversely affect and alter a child's physiologic functioning and epigenetic expression, altering the developing immunologic and hormonal systems, further impacting their emotional and cognitive systems [2]. These physiological and developmental changes findings have led the American Academy of Pediatrics (AAP) to acknowledged childhood trauma and toxic stress as foundational causes of morbidity and mortality [3]. In the United States, it was estimated that in 2008 the total lifetime economic burden associated with childhood trauma was approximately \$124 billion. This economic burden rivals the cost of other high-profile public health problems, such as stroke and type 2 diabetes. The lasting effects of childhood trauma and toxic stress have multi-generational consequences due to the perpetuation of the Cycle of Trauma and Health Disparities.

CYCLE OF TRAUMA AND HEALTH DISPARITIES

The Cycle of Trauma and Health Disparities is based on the Break the Cycle model for children's environmental health disparities. Abuse, neglect, and household dysfunction are examples of ACEs that the patient is exposed to during the developing years (single black circle). These events have been shown to disrupt neurological and physical development, as the child's physiological response to stress becomes dysregulated. The ongoing stress leads to both hypertrophy and over activity in the amygdala and a decrease in neural connections between the limbic system and the hippocampus, which is involved in memory function, and medial prefrontal cortex, which is involved in executive functioning and decision-making (double black circle) [7]. These changes in brain development and connectivity lead to impaired memory, disordered mood, and a lack of inhibitory control which can lead to maladaptive behavioral responses such as addictive behaviors or violence. In adulthood, and as parents, the maladaptive behaviors and poor mental and physical health will have a detrimental impact on their provision of a nurturing, resourceful environment for their children and increase the likelihood that their children will also experience ACEs [3], perpetuating what we are calling the "Cycle of trauma and health disparities."

Health care delivery systems and pediatric providers in particular, are in a unique position to identify both risk and resilience factors for the healthy development of the children and their families in their care. In response to the large and devastating burden on individual health as well as the great economic and public health burden caused by childhood trauma, the AAP issued a policy statement urging pediatricians to focus on early screening, prevention, and interventions to manage childhood trauma and toxic stress in their practices [4]. However, in the primary care setting, a major stumbling block to addressing this issue is the availability of efficient ways to identify patients and families at risk for, or experiencing current trauma or the adverse effects of past childhood trauma. Moreover, there are few

evidenced-based trauma-informed interventions that can be implemented in a busy primary care practice. The goal of our project was to develop a process for addressing ACEs in a pediatric primary care clinic with an existing integrated Behavioral Health and Resource team. The clinic Behavioral Health and Resource Team is led by a clinical psychologist and a clinical social worker, and consists of undergraduate and graduate level social workers, as well as doctoral level psychology students [8]. The team was developed to perform assessments, brief interventions, and referrals in response to same-visit concerns identified by the pediatrician, as well as consults to address a variety of concerns [9]. Research included baseline assessment of clinic provider and parent/caregiver knowledge and perceptions of ACEs, development and pilot testing of an ACEs screening, brief intervention, and referral protocol, and collection of parent/caregiver feedback on screening.

Figure 1. Cycle of trauma and health disparities.

The long-term goal of this work is to inform approaches for the Pediatric Primary Care Setting that will help to break the Cycle of Trauma and Health Disparities. The circled areas are those that are addressed through our screening, brief intervention, and referral program.

OUR STUDY

The setting for this study was an academic pediatric primary care clinic with an existing integrated Behavioral Health and Resource Team located in South Central Appalachia. Eighty-five percent of the children served by the clinic are publicly-insured. In order to qualify for government funded health insurance, a family of four must earn less than \$34,248 per year, which is at 138% of the federal poverty line in 2018. Procedures were reviewed and approved by the East Tennessee State University Institutional Review Board.

Phase I. Knowledge of ACEs

Healthcare providers, who were not previously instructed on ACEs or ACEs screening in the clinic were invited to complete a survey on their knowledge of ACEs and their beliefs about how ACEs affect parents and children. Additionally, parents/caregivers 18 years of age or older visiting a health education table at a local community event were invited to complete the same survey. After being provided with a definition of ACEs, participants were first asked if they had heard of the term “ACEs” before. Next, using a 5-point Likert-type scale, they were asked to rate their knowledge and perceptions of how ACEs impact children’s behavior, adult mental and physical health, and parenting, as well as how support systems may counteract the effects of ACEs. Responses were entered into an Excel spreadsheet and analyzed using IBM SPSS Statistics. Survey collection occurred in July 2017.

Phase II. Screening and Intervention Protocol Development

A “Champion Team” consisting of medical, psychology, social work, nursing, case management, and community home visiting providers developed a new protocol for ACEs screening in the clinic using funding from a State of Tennessee *Building Strong Brains* grant. The team also facilitated training on ACEs and the new protocol for healthcare providers and staff in the clinic using resources from Substance Abuse and Mental Health Services Administration and Tennessee’s Building Strong Brains including discussion of how to communicate about scores with families [10]. The Center for Youth Wellness ACE-Questionnaire (CYW-ACE-Q) was adapted for use as a self-administered parent screener and child screener by parent/caregiver proxy [11]. The CYW ACE-Q is intended for use in pediatric and family practice settings and is available in three age-specific versions and in English and Spanish. It takes approximately two to five minutes to complete the questionnaire.

Screening Questionnaire included a list of ACEs and asked the respondent to simply list the number experienced out of a possible total of ten. Due to concerns about mandatory reporting requirements, a question was added to the child screener asking the respondent to separately indicate if the following two ACEs had been experienced: “Someone pushed, grabbed, slapped, or threw something at your child OR your child was hit so hard that your child was injured or had marks,” and/or “Someone touched your child’s private parts or asked your child to touch their private parts in a sexual way.” Screeners were distributed by the nurse during check-in for their scheduled clinic visit along with an educational resource handout on ACEs and resilience developed by the Champion Team. Education on childhood trauma and resiliency and the proposed screening protocol was provided to all clinicians and staff by the Champion Team. Parent/caregiver screeners were administered at the 1-month well child visit or first visit to the clinic. The child screeners were administered during the 12 month - 5-year annual well-child visits. Scores from the screening questionnaires were documented in the electronic health record (EHR) and discussed by the provider during the encounter. After receiving a brief summary of the clinician’s concerns, also referred to as a “warm handoff,” for a patient’s elevated ACE scores or other behavior/social issues, the

clinic Behavioral Health and Resource Team offered further assessment, resources, and support.

Families with an ACE score of 2 or higher were offered education and resources including *The Incredible Years Well Baby Program* (TIY), during well child visits in the first 9 months of life [11]. TIY is designed to promote emotional and social competence and to prevent, reduce, and treat aggression and emotional problems in young children. The ultimate goal of TIY is to reduce the chance of developing later delinquent or at-risk behaviors [12]. It has also been evaluated as a prevention program with children who are at risk for delinquent or high-risk behaviors because of family or demographic factors such as poverty, parental mental health problems, or poor parenting skills. The Well Baby Program was recently developed for use in the primary care setting. This program consisted of watching and discussing an age-appropriate video of parent-child interactions with a team member during the visit. A summary handout of parenting tips from the program was also provided.

Families with an ACE score of 4 or higher received education and resources from the Behavioral Health and Resource Team and were invited to participate in home or group visits including up to 10 hours of *Nurturing Parenting* (NP) [13]. NP is an evidence-based program shown to improve parenting skills, problem solving, communication, and developmentally-appropriate expectations and to decrease violence in families at high risk of child maltreatment within diverse populations [13, 14].

All families seen during this period for well child visits were provided with locally-developed *ReadNPlay for a Bright Future* materials and *Reach Out and Read* books and were referred to *ReadNPlay* family community events [15]. Care was coordinated for referred patients during bimonthly team conferences.

The number of patients and parents/caregivers with elevated screening results referred to the parenting programs was abstracted from the EHR on a monthly basis during the project period (October 1, 2017-June 30, 2018). Percentages were calculated based on the number of well child visits performed with screener administered during the project period.

Due to funding constraints, the local Nurturing Parenting program referral resource was discontinued during phase three.

Phase III. Parent/Caregiver Feedback on Screening

A survey was constructed to assess parent/caregiver perceptions of acceptability, appropriateness, and feasibility of ACEs screening and interventions. The surveys were developed using the Acceptability of Intervention Measure (AIM), Intervention Appropriateness Measure (IAM), and Feasibility of Intervention Measure framework. Each construct was evaluated with four-item measures of implementation outcomes that are often considered “leading indicators” of implementation success [16]. Each indicator was graded on a 1 to 5 scale, with 1 being completely disagree and 5 being completely agree using the following acceptability, appropriateness and feasibility constructs:

Our team created study flyers containing information about ACEs and ACEs scores, which were offered to parents who completed an ACE-Q screener during their child’s office visit in one of three resident continuity clinics during April-May 2019. Parents who wished to complete a feedback survey did so after the visit before leaving clinic. As compensation for

their time, parents were offered a small toy or book for their child at the completion of feedback survey. Survey data was entered into IBM SPSS Statistics and summarized descriptively using means, standard deviations, and percentages. A summary mean of the four items for acceptability, feasibility, and appropriateness was also calculated.

FINDINGS

During the first phase of the study, 51 parents/caregivers and 16 healthcare providers in the clinic were surveyed in Summer 2017. Results are shown in Table 1 and Figures 1 and 2. The majority of the respondents were white females within the 25-44 years age group. Fewer than one-third of parents/caregivers in this sample had heard of the term “ACEs” prior to receiving this survey. However, after being provided with a definition of ACEs, most respondents agreed that ACEs could affect children's behavior and adult mental health.

Table 1. Demographic and Baseline Characteristics of Study Population in Phase I

	Parents/Caregivers (n = 51)	Healthcare Providers (n = 16)
Gender		
Female	78.4%	93.8%
Male	21.6%	6.3%
Age (Years)		
18-24	5.9%	12.5%
25-34	23.5%	50%
35-44	43.1%	12.5%
45-54	11.8%	12.5%
≥55	15.7%	12.5%
Race/Ethnicity		
White	84.3%	87.5%
Hispanic/Latino	3.9%	0%
Black/African American	7.8%	0%
Asian/Pacific Islander	3.9%	12.5%
Heard of ACEs before	27.5%	50%

Table 2. Demographic characteristics of parent/caregiver ACE-Q screening feedback survey respondents during Phase III

Parent/Caregiver Demographics	# (%)
Age	
18-24 years	7 (41.2%)
25-34 years	6 (35.3%)
35-44 years	1 (5.9%)
45-54 years	2 (11.8%)
55-64 years	0
65 or older	1 (5.9%)
Race/Ethnicity	
Caucasian	15 (88.2%)
Hispanic	2 (11.8%)
Gender	
Female	13 (76.5%)
Male	4 (23.5%)

Agreement was less for perceptions of effects on physical health in adults. Most respondents recognized that a parent’s own ACE exposure could make parenting more difficult and that having a strong support system is helpful in counteracting these negative effects. At the start of the study, it was surprising that only half of healthcare providers were familiar with the term ACEs. After being provided with a definition of ACEs, most healthcare providers agreed that multiple ACEs can have adverse effects on children and adults.

Figure 2. Knowledge and Perceptions of Parents/Caregivers about ACEs (n = 51) Phase I.

Figure 3. Knowledge and Perceptions of Health Professionals about ACEs (n = 16): Phase I.

Phase II: ACEs Screening and Intervention Protocol Development and Pilot-Testing

Among the 96 parents/caregivers screened, 37.5% reported an ACE score of four or higher and 53.1% reported an ACE score of two or higher for themselves. Out of 66 child screeners completed for children 1-5 years of age, parents/caregivers reported ACEs score of four or higher in 3% of children. Based on our screening protocol, we referred over one third of families for Nurturing Parenting and over one half of patient families with infants 1-9 months of age for TIY.

Table 3. Means and standard deviations for acceptability, feasibility, and appropriateness items (1 = Completely Disagree; 2 = Disagree; 3 = Neutral, 4 = Agree, 5 = Completely Agree)

Question	Mean (standard deviation)
Acceptability	Possible range: 1-5
The ACE-Q screening during my office visit meets my approval	4.89 (0.323)
The ACE-Q screening during my office visit is appealing to me	4.78 (0.428)
I liked the ACE-Q screening during my office visit	4.78 (0.428)
I welcome ACE-Q screening during my office visit	4.78 (0.428)
Feasibility	Possible range 1-5
ACE-Q screening seems fitting during my child's office visit	4.72 (0.575)
ACE-Q screening seems suitable during my child's office visit	4.67 (0.594)
ACE-Q screening seems applicable during my child's office visit	4.33 (1.029)
ACE-Q screening seems like a good match for my child and my family	4.00 (1.085)
Appropriateness	Possible range: 1-5
ACE-Q screening seems implementable during my child's doctor visit	4.28 (0.826)
ACE-Q screening seems possible during my child's doctor visit	4.33 (0.907)
ACE-Q screening seems doable during my child's doctor visit	4.44 (0.784)
ACE-Q screening seems easy to use	4.67 (0.594)

A total of 18 out of 29 parents/caregivers screened for ACEs during the project period completed a feedback survey (62%). Results are shown in Tables 2 and 3. The mean summary scores for acceptability, feasibility, and appropriateness were 4.80, 4.33, and 4.43, respectively. Only two parents/caregivers completed a feedback survey on TIY, but also described it as feasible, acceptable and appropriate. The surveys filled out by both these parents shows that they marked a grade of 5 for each question on the survey provided, thus the parents strongly agreed with the intervention of the TIY. TIY was provided to only three families during the project period due to a small number of infants seen in the continuity clinics.

DISCUSSION

In this study, we assessed the baseline knowledge and perceptions of ACEs among a sample of our clinic providers and local parents/caregivers attending the clinic with their children. We then developed and pilot tested an ACEs screening, brief intervention, and

referral protocol for families with children 5 years of age and younger in a pediatric primary care clinic with an integrated Behavioral Health and Resource Team. Following implementation of the protocol, we assessed parent/caregiver feedback on ACEs screening during well child visits. ACEs screening was imperative to better understand our patient population in hope of providing those at increased risk of negative health outcomes with resources to help build resilience. In order to break the cycle of trauma and health disparities, it is imperative to identify the families experiencing trauma and to intervene as early in the life of the child as possible. Early intervention is protective against the adverse effects of toxic stress on brain development and connectivity, which can lead to impaired memory, disordered mood, and a lack of inhibitory control with regards to impulsive behavior. Thus, early intervention can be preventative against maladaptive behavioral responses such as addictive behaviors or violence [7]. However, prior to our intervention, we found that less than one-third of parents/caregivers and only 50% of healthcare providers in the clinic were familiar with ACEs, suggesting a need for education among families and healthcare providers. Indeed, national data from 302 general pediatricians participating in the 2013 American Academy of Pediatrics Periodic Survey revealed that only 11% were very or somewhat familiar with the ACE study [17]. Thus, our providers were found to have baseline for ACEs awareness greater than that found in a national survey. This finding is likely due to the population that our clinic serves, as 85% of our patients are publicly-insured. Nonetheless, these data suggest additional training of pediatric providers is needed to increase understanding of ACEs and long-term health outcomes.

Multiple research papers have demonstrated a graded dose-response relationship between the number of ACEs a person experienced and their health-risk behaviors [3]. As the strength of the literature and evidence has grown, ACEs scores have now been linked, in the same graded dose-response relationship, to more than 40 health outcomes [18]. An example particularly relevant to the Appalachia due to the opioid drug crisis, involves the graded risk increase for drug use with increasing ACEs scores. In a 2018 research paper, Tilson investigated opioid use and ACEs within the population of North Carolina and found that each ACE increased the likelihood for early initiation of drug use by 2- to 4-fold [19]. Compared with people with no ACEs, people with $>$ or $=$ 5 ACEs were 7- to 10-fold more likely to report drug use problems, addiction, and parenteral drug use [19]. These alarming findings highlight the importance of mitigating the effects of ACEs, and the need for sufficient resources to assist families with high ACE scores and is also a pre-requisite for an effective screening program. We found that the prevalence of ACEs was high in our clinic population with ACE scores of four or higher reported for 37.5% of the parents and 3% of children. An ACE score of two or higher was reported for 53.1% of parents/caregivers. Based on our screening protocol, we referred over one third of families for Nurturing Parenting and over one half of patient families for the IY. Maintaining sufficient resources to meet these needs was a challenge, and funding for Nurturing Parenting was lost during the project period. At the same time, our findings identified a large number of at-risk families, suggesting that development of additional resources should be a priority, for local community clinics such as ours to the state and federal government. The direct cost childhood trauma is measured in the billions, and the downstream effects of improved screening and appropriate and adequate interventions for those affected, has the potential to decrease the rates high cost high burden disease such as obesity, heart disease and diabetes.

Notably, the rate of reported ACEs in our clinic was higher than that found in Tennessee or nationally. In 2014 in Tennessee, 17% of adults reported having experienced four or more ACEs while 42% reported two or more [20]. The high percentage of ACEs among patients and parents/caregivers in our clinic was not unexpected due to the relatively low socioeconomic status of our clinic population and the high rates of maternal opioid use disorder and neonatal abstinence syndrome in Northeast Tennessee [21, 22]. Recent Behavioral Risk Factor Surveillance System (BRFSS) ACE data from 2011-2014 showed that nationally, 15.8% of adults reported 4 or more ACEs, and 38% reported an ACE score of 2 or more [20]. Estimating the magnitude of families affected by ACEs in a pediatric primary care practice can aid in the development and allocation of services and resources.

The ACE-Q screener used in Phase II was suitable for our study population as most parents/caregivers who completed the feedback survey reported the screening as appropriate, feasible, and acceptable to them as part of a well-child visit. Providers in our clinic received training on ACEs prior to initiating screening, including on how to discuss scores with families with sensitivity, and our clinic was equipped with a Behavioral Health and Resource Team to provide support to families experiencing ACEs. Similarly, a study published in 2018 using thematic interviews with parents of children under 6 years of age attending an urban pediatric clinic found consistent support for ACEs screening for the purpose of linking to services as well as recognition of the intergenerational nature of ACEs [23]. Surveys conducted with 152 predominantly Latino adults attending a federally qualified health center found that, following screening, 86% of respondents were comfortable with ACEs screening [24]. In larger study of 480 pregnant women screened at 14-23 weeks gestation, over 90% were somewhat or very comfortable completing screeners and discussing results with their physician [24]. Eighty five percent somewhat or strongly agreed that clinicians should ask prenatal patients about their ACEs [25].

The American Academy of Pediatrics published a policy statement on Toxic Stress, much of which is a result of ACEs [6]. Among their set of recommendations for pediatric practices was to institute screening of families at high risk for ACEs and Toxic Stress and then to provide targeted support for the parents and other caregivers by addressing key social and economic stressors through targeted referrals and by enhancing the caretakers' parenting competence [6]. A potential barrier to ACEs screening is the burden on families and clinic staff at well-child visits. To address this barrier, electronic screening tools can be sent to families via email before the clinic visit. Allowing a family to fill out some of the screeners before they come to the clinic may save time during the visit and reduce the burden on families and staff. However, complete follow up of families with positive screening results reported prior to the visit may be challenging in populations with high "no-show" rates for visits, meaning the patient does not attend their recommended well child visits. Effective screening and intervention often require partnership with external agencies such as early intervention and other social services. In our practice, children have access to a Behavioral Health Resource team which includes a child psychologist and a social worker, who work in close partnerships with local social services such as Tennessee Early Intervention Services, Youth Village, and multiple behavioral therapists. However, most outpatient pediatrics clinics do not have a Behavioral Health Resource team, which can make it more challenging to access local resources or simply are situated in a region that does not have these providers. The lack of availability of expertise and partnerships with community resources to address ACEs is another potential barrier to primary care screening. Integrating professionals who can

provide behavioral health and social services into primary care offices can address this barrier and improve access to needed services and resources.

In this project, we were able to initiate an ACEs screening protocol for a pediatric primary care clinic, which enabled identification of at-risk families. ACEs screening was positively perceived by most parents/caregivers. Approaches to addressing childhood trauma and considerations for ACEs screening in primary care setting has been discussed elsewhere in depth [4, 5, 8, 9]. Our experience suggests that identifying provider training needs, considering parent/caregiver perceptions and preferences, and assessing resource needs are helpful initial steps. The presence of integrated behavioral health and social services in a clinic setting can be invaluable in addressing the needs of families at-risk for experiencing challenges because of their ACE score.

CONCLUSION

Given the high prevalence of ACEs and toxic stress and the high burden of down-stream physical and mental health problems related to these exposures, it is imperative to continue to explore optimal approaches for primary care practices to integrate screening protocols to identify families at risk, to develop sensitive and skilled staff to assist families, and to build partnerships with community organizations that can help support families, prevent ACEs, and break the cycle of trauma and health disparities.

Chapter 337

EDUCATING CLINIC SUPPORT STAFF TO ENHANCE EARLY LEARNING ENVIRONMENTS THROUGH PEDIATRIC WELL-CHILD VISITS

***Cori Walker, Asher Liu, Snigdha Gupta,
Fuad Baroodi, MD and Dana Suskind*, MD***

TMW Center for Early Learning and Public Health,
University of Chicago, Chicago, Illinois, USA

ABSTRACT

A rich early language environment in the first years of life is important for optimal language and cognitive development. Socioeconomic disadvantage in a child's early language environment can have long-term impacts on educational attainment, employment opportunities, and health outcomes. In an effort to enhance the early language milieu for children from low-income households, this study aims to 1) improve pediatric clinic support staff's knowledge about early cognitive and language development and 2) positively influence their perceptions of the role they can play in educating parents/caregivers about the importance of early language exposure in the first three years of life. The study was run as a quasi-experimental, One-Group, Pretest-Posttest Design. The participants were pediatric clinic support staff members from four clinics in the Chicago area ($n = 58$). Participants' knowledge and perceptions were assessed one week prior to a curriculum presentation intervention and immediately following the intervention. Analysis showed a significant increase in participants' knowledge of early cognitive and language development post-intervention (infancy: $M = 24.74$ vs. $M = 28.05$, $P = 9.63E-09$; early childhood: $M = 25.78$ vs. $M = 29.90$, $P = 1.39E-11$). Clinic support staff also reported that after attending the presentation, they felt more comfortable and were more likely to discuss these topics with parents/caregivers in clinic. This study highlights the importance of educating clinic staff about early language and cognitive development and informing them of the crucial role they can play in

helping to enhance early language environments for their young patients, particularly those from low socioeconomic backgrounds.

INTRODUCTION

The first three years of life are said to be the most important for cognitive and language development. During this period, new neural connections are formed at a rate of over 1 million per second [1]. Early social experiences and rich language interactions with nurturing caregivers are critical for this rapid brain development and set the foundation for future learning [2, 3]. A child's early language environment is an important, yet often overlooked, social determinant of health [4]. Research suggests that disparities in the quality of this early language environment exist and disproportionately affect those in poverty [5]. These disparities have been shown to negatively impact brain growth—as well as future educational, occupational, and health outcomes—among socioeconomically disadvantaged children [6-8].

Research shows that the negative impacts of poverty on brain development become apparent well before children enroll in school. In a longitudinal study by Tamara Halle et al. [9], nine-month old infants in families of low socioeconomic status (SES) scored lower on cognitive development assessments than their peers. This disparity tripled in severity by 24 months of age. That being so, programs aimed at supporting children's cognitive development after they begin school may come too late to alter the trajectories of children's neurocognitive development. [10]. Therefore, interventions in the critical first three years of life are necessary to prevent such disparities at their onset.

Parents and caregivers in the home are the key mediators of a child's early learning environment. Disparities in early social interactions and language input among children from differing SES backgrounds have been attributed to differences in parental knowledge of infant development [11, 12]. Further, parental knowledge about the importance of early language exposure has been shown to be predictive of parental behaviors with their children [13]. These behaviors inform the quality of adult-child interactions and a child's early language environment. This environment sets the foundation for a child's brain and language development, which sets the basis for their school readiness and educational attainment. Lower educational attainment has been shown to result in decreased employment opportunities, limited residential options, and ultimately, poor health outcomes [4]. The diagram below represents this cycle of early learning disparities.

Fortunately, studies have shown that well-planned, parent-directed interventions in low-income populations can significantly improve various parenting behaviors with their children [14]. Therefore, interventions to empower all parents with increased knowledge of early brain development and everyday strategies to enrich their children's early language environments represent a promising opportunity to reduce educational inequities and subsequently break the cycle of early learning disparities.

There are 12 recommended routine well-child pediatric visits during the first three years of life [15]. As a result, pediatricians and pediatric clinic staff are uniquely positioned to intervene during this critical period of foundational brain development. In fact, in 2017, the American Academy of Pediatrics established 'early brain and cognitive development' as an integrated child health priority in their "Agenda for children" [16]. However, while studies have shown that parents want more information on early childhood learning at pediatric visits,

they do not regularly receive this desired insight [17]. A recent study surveying 236 parents in Chicago area clinics found that only a minority of parents reported receiving information on cognitive development topics at well-child visits, such as “brain growth” (25.8%), “how babies learn” (13.1%), and “learning to talk” (9.3%) [18].

Figure 1. The cycle of early learning disparities.

Figure 2. Use of pediatric clinics to break the cycle of early learning disparities.

While pediatricians are often considered the primary source of guidance for parents, they have a large mandate to cover in the relatively brief, well-child visit and may not have the time to engage families and emphasize all anticipatory guidance topics equally [19, 20]. The clinical support staff can play a meaningful role in actively engaging families by providing information about language interactions and enhancing discussions of important topics during clinic visits [21]. Therefore, with the objective to break the cycle of early learning disparities

(see Figure 1), this study intends to use pediatric clinics - and more specifically, the support staff in these clinics - as an access point to positively impact parental knowledge of early brain development (see Figure 2). Our study aimed to create, deliver, and test a curriculum intervention designed to improve pediatric clinic support staff's knowledge about early cognitive and language development, and positively influence their perceptions of the role they can play in educating parents/caregivers about the importance of early language environments during pediatric clinic visits. We hypothesized that after attending our intervention, study participants would exhibit improved knowledge and report increased comfort and likelihood to engage in discussion of these topics with parents during well-child visits. The ultimate goal of this intervention was to see if we could cultivate a pediatric clinic culture that identifies early cognitive and language development as a priority, and considers educating parents on this topic a standard of care.

OUR STUDY

This study was conducted at four pediatric clinics that serve predominantly families with public assistance in the Chicago area. The study began in December 2018 and concluded in February 2019. The clinics were identified through email correspondence with clinic coordinators or directors. All pediatric clinic staff other than the physicians (i.e., nurses, medical assistants, laboratory technicians, receptionists, etc.) were asked to volunteer to participate in the study, including attending an intervention and responding to surveys at their clinic. Staff members were eligible to participate if they were at least 18 years old and English-speaking. Participants were verbally consented prior to the curriculum intervention and received a \$50 gift card as compensation. The Biological Sciences Division Institutional Review Board at the University of Chicago Medicine (IRB#12-1172-CR006) approved this study.

Intervention

A curriculum intervention was developed specifically for pediatric clinic support staff. The multimedia curriculum included an explanation of the science behind early cognitive and language development as well as common misconceptions about these topics and specific strategies and examples for addressing these topics with parents in clinic. The intervention was delivered in the form of an in-person, group presentation at each clinic.

Measures

A demographics questionnaire was administered to study participants about one week prior to the curriculum intervention. Paper versions of the questionnaires were delivered to the clinic for participants to complete at their leisure. The completed questionnaires were collected from the clinic about two days prior to the scheduled intervention date.

Knowledge

Along with the demographics questionnaire, participants completed the Scale of Parent/Provider Expectations and Knowledge (SPEAK) [22]. The SPEAK assesses providers' expectations on developmental milestones and their knowledge about the role of caregiver responsiveness and inputs in children's cognitive and language development during infancy (birth-6 months) and early childhood (birth-5 years). Participants responded to 1 item on a 6-point scale, ranging from 0 (in elementary school, 6 years and up) to 5 (as an infant, 0 to 6 months), and 17 items on a 4-point scale, ranging from 0 (definitely true) to 3 (definitely not true). Two SPEAK sum scores including Infancy ($\alpha = .74$) and Early Childhood ($\alpha = .72$) were calculated. Higher scores represented more knowledge. This questionnaire was administered to participants a second time immediately following the curriculum intervention.

Beliefs

Participants were given qualitative questions to assess their initial beliefs about educating parents on early cognitive development and the importance of early language exposure. Multiple choice questions assessed what role the participants believed they had in educating parents and their comfort level in doing so. Post-intervention questions assessed if participants found the presentation useful and whether or not it made them feel more comfortable discussing topics such as early language and cognitive development with parents during well-child visits.

Reported Behaviors

To assess baseline behaviors, a pre-intervention question asked the participants if they currently discuss early language and brain development with parents/caregivers of infants.

Table 1. Participant demographics

Variable		Category	% (n = 58)
Age		18-24	3.4
		25-34	36.2
		35-44	25.9
		45-54	22.4
		55-64	12.1
		65+	0
Sex		Female	86.2
		Male	8.6
		Prefer not to answer	5.2
Race	Hispanic or Latino	Any race	27.6
	Non-Hispanic	Black or African American	46.6
		White	10.3
		Asian or Pacific Islander	3.5
		Multiracial	1.7
	Prefer not to answer		10.3

Perceived barriers to discussing these topics with parents, along with potential solutions to these barriers, were evaluated with checklist items and free response. Post intervention, participants were asked whether or not the curriculum presentation made them more likely to discuss early language and cognitive development with parents of young children during well-child visits.

Statistical Analysis

Two SPEAK score sums, i.e., infancy (birth-6 months) and early childhood (birth-5 years), for each participant were calculated from the pre- and post-intervention SPEAK surveys. Pre- and post-intervention scores were compared using two-tailed t-tests in Microsoft Excel. In order to investigate whether the intervention had similar effects on participants with varying education, we compared the baseline and post-intervention SPEAK scores among participants with high education (Bachelor's degree or above) and participants with low education (less than Bachelor's degree) separately. Responses to pre- and post-intervention qualitative questions were tallied and the percentages of each response on pre-intervention questions were compared to those from the post-intervention questions.

FINDINGS

The sample included 58 clinic staff members with a 90.6% retention rate among the 64 participants recruited originally. The majority of participants were female (86.2%) mainly in the 25-34 and 35-44 age ranges (36.2% and 25.9%, respectively; see Table 1). Most participants identified as Black or African American (46.6%), followed by English-speaking Hispanic or Latino participants of any race (27.6%, see Table 1). For education level, the majority of study participants had completed some college credit, technical training or an associate's degree, but had not obtained a bachelor's degree (60.3%; see Table 2).

Table 2. Participant education and job title

Variable	Category	% (n = 58)
Education level	High school graduate, or equivalent (GED)	8.6
	Some college credit, no degree	20.7
	Technical training	24.1
	Associate degree	15.5
	Bachelor's degree	17.2
	Postgraduate degree	12.1
	No response	1.7
Job Title	Medical Assistant	37.9
	Registration/Receptionist/Referral Coordinator/PSR	15.5
	Nurse	13.8
	Manager/Clinic Coordinator	6.9
	Lab Tech	5.2
	Social Worker/Case Manager	5.2
	Medical Interpreter	3.4
	Maintenance/Security	3.4
	Nurse Practitioner	1.7
	Lactation Specialist	1.7
	OutReach Manager	1.7
	Healthy Steps Specialist	1.7
	No response	1.7

Participants held a variety of job titles within the clinics. The largest group was Medical Assistants (37.9%) followed by roles that involved assisting patients at the clinic's front desk (i.e., Registration, Receptionist, Referral Coordinator, Patient Service Representative; 15.5%; see Table 2). The third largest group of participants was Nurses (13.8%).

Knowledge

There was a significant increase in Infancy SPEAK scores from baseline ($M = 24.74$, $SD = 4.18$) to post-intervention ($M = 28.05$, $SD = 2.90$; see Table 3). There was also a significant increase in Early Childhood SPEAK scores from baseline ($M = 25.78$, $SD = 4.37$) to post-intervention ($M = 29.90$, $SD = 2.67$; see Table 4). When comparing baseline and post-intervention SPEAK scores by participant education level (less than Bachelor's degree and Bachelor's degree or above), there was a significant increase in SPEAK scores from baseline to post-intervention for both education levels (see Tables 5 and 6).

Table 3. Infancy SPEAK change in knowledge

	Mean	N	SD	SE Mean	t	df	Significance
Baseline	24.74	58	4.18	.549			
Post-Intervention	28.05	58	2.90	.381	-6.711	57	9.63E-09

Table 4. Early childhood SPEAK change in knowledge

	Mean	N	SD	SE Mean	t	df	Significance
Baseline	25.78	58	4.37	.574			
Post-Intervention	29.90	58	2.67	.350	-8.418	57	1.39E-11

Table 5. Infancy SPEAK change in knowledge by education level

Education Level	Time Point	Mean	N	SD	SE Mean	t	df	Significance
Less than Bachelor's Degree	Baseline	24.70	40	4.046	0.640			
	Post-Intervention	27.98	40	3.084	0.488	-5.344	39	0.000
Bachelor's Degree or Higher	Baseline	24.94	17	4.710	1.142			
	Post-Intervention	28.18	17	2.604	0.631	-3.673	16	0.002

Table 6. Early childhood SPEAK change in knowledge by education level

Education Level	Time Point	Mean	N	SD	SE Mean	t	df	Significance
Less than Bachelor's Degree	Baseline	25.85	40	3.718	0.588			
	Post-Intervention	29.83	40	2.735	0.432	-7.493	39	0.000
Bachelor's Degree or Higher	Baseline	25.88	17	5.732	1.390			
	Post-Intervention	29.94	17	2.609	0.633	-3.833	16	0.001

Beliefs

Prior to the curriculum intervention, participants were asked to respond to the statement "In my role, I feel comfortable sharing information about children's language and brain development with parents/caregivers of infants." Responses greatly varied with 10.5%

“Strongly Agree,” 47.4% “Agree,” 31.6% “Disagree,” and 10.5% “Strongly Disagree” (N = 57). Participants were also asked to gauge what role they thought they played “in teaching parents about their child’s early language and brain development.” 35% of study participants felt that they played either a “Significant” or “Moderate Role” in this, while 36.8% responded “Minor Role” and 24.6% responded “No Role” (N = 58).

After the curriculum intervention, 100% of study participants replied “Strongly Agree” or “Agree” to finding the presentation useful. 98.3% reported “Strongly Agree” or “Agree” to the statement: “The strategies presented in this curriculum make me more comfortable discussing topics such as early language and cognitive development with parents during well-child visits” (N = 58).

Reported Behaviors

On the pre-intervention survey, 81% of participants answered “Never” or “Not Often” when asked if they “currently discuss early language and brain development with parents/caregivers of infants” (N = 58). “No expertise in this topic” was the most selected reason for what prevents participants from discussing these topics in their interactions with parents/caregivers. (50%; see Table 7). Participants felt that having pamphlets to provide parents (69%) and more training on the topic (65.5%) would make them more likely to talk about early language and brain development in their interactions with parents/caregivers of infants (see Table 8).

Table 7. Perceived Barriers to discussions. Some themes among free response answers from participants that selected “Other” include limited interactions with parents/ patients, feeling that other professionals in clinic should have these discussions with parents, and not wanting to spread false information

What prevents you from discussing early language and brain development in your interactions with parents/caregivers of infants? (Select all that apply)	%
Time constraints	39.7
No expertise in this topic	50.0
More important topics to discuss with parents	1.7
Difficult topic for parents/caregivers to understand	6.9
Not a part of my job description	37.9
Other	13.8

Table 8. Reported items to increase likelihood of discussions. Free response answers from participants that selected “Other” either reiterated the need for more training on this topic or stated that having these discussions is not a part of their job description

What are some things that would make you more likely to talk about early language and brain development in your interactions with parents/caregivers of infants? (Select all that apply.)	%
More time	43.1
More training on the topic	65.5
Having pamphlets to provide parents	69.0
Making this an EMR checklist item to discuss	15.5
Financial incentive	8.6
Other	15.5

After attending the curriculum intervention, 100% of study participants stated that they “Agree” or “Strongly agree” with the statement: “I am more likely to discuss early language and cognitive development with parents of young children during well-child visits” (N = 58).

DISCUSSION

Rich language environments, shaped by nurturing adult-child interactions, are critical to building children’s brains in the first three years of life. Disparities in early language environments exist and disproportionately affect those in poverty. Not only do these early learning disparities negatively impact children’s cognitive and language development, they also have long-term impacts on educational attainment, future employment and economic security, and health outcomes. Because parents are the key mediators of a child’s learning environment during this early period, impacting parental knowledge of early brain development, and consequently impacting their interactions with their children, is a pivotal step in breaking the cycle of early learning disparities. In an effort to leverage the touchpoints that well-child visits offer, this study aimed to enhance pediatric clinic support staff’s knowledge about early language and cognitive development and impact their beliefs about the critical role they can play in educating parents about the importance of early interactions. The study was conducted in four pediatric clinics, and the intervention included an in-person curriculum presentation focused on the science of early brain development, the role of pediatric clinic support staff, and strategies to discuss brain and language development with parents during well-child visits.

Findings of the present study demonstrate an increase in knowledge of early cognitive and language development among pediatric clinic support staff after attending the educational presentation. The study also reveals that the staff members are more willing to discuss these topics with parents when they feel properly equipped to do so. The commonly reported lack of expertise on early brain and language development, and the need for more training on this topic in order to discuss with parents, can be addressed by providing the support staff with the education they desire, as well as easy-to-implement strategies to promote these discussions with parents in clinic. The findings of our study show that the curriculum intervention we created had an immediate positive impact on knowledge of early cognitive and language development for staff members regardless of their varying levels of education.

This study demonstrates the need for providing ongoing education to the clinic support staff and supporting them with tools and strategies to engage parents. Using their unique access to families, pediatric office staff can promote the importance of early language environments and encourage families to have rich language interactions with their children. Utilizing all pediatric clinic support staff to participate in these discussions with parents and caregivers can directly enhance patient access to important information during clinic visits [23]. It can also improve overall clinic efficiency and ensure providers feel well supported, and clinic support staff feel more empowered to support parents [24, 25]. These discussions with parents may have immediate positive effects on the parent-child relationship, and with continued reinforcement, could potentially contribute to long-term positive educational outcomes for all children.

Limitations

Some limitations of this study should be noted. As a quasi-experimental design, our study lacks a control group and randomization. Although participants reported an increased likelihood to discuss brain and language development with parents in clinic, our study did not include any behavior measures to assess if these discussions did increase post-intervention. A longer study timeline would allow for the addition of these behavior measures and a third SPEAK assessment at a later point in time to measure for retention of the knowledge gained from our intervention. It is also not clear whether changes in clinic staff behavior would have a significant impact on child developmental outcomes, which is the ultimate goal of this effort. Future research might be able to examine this aspect more fully.

CONCLUSION

This study highlights a valuable opportunity for educating pediatric clinic support staff about early language and cognitive development and the important role they may play in enhancing early language environments for their patients. Providing training to pediatric clinic staff may help increase awareness of the importance of early language exposure, but further studies are needed to investigate the true impact of this intervention on the quantity and quality of discussions with parents in clinic. Leveraging the routine well-child visits and all clinic staff members to make these discussions a standard of care has the potential to help break the cycle of early learning disparities experienced by socioeconomically disadvantaged children at their earliest onset.

Chapter 338

CONTEXTUALIZING THE SOCIAL AND STRUCTURAL CONSTRAINTS OF ACCESSING AUTISM SERVICES AMONG SINGLE BLACK FEMALE CAREGIVERS

Alice Hong and Jennifer S. Singh*, PhD

Georgia Institute of Technology, School of History and Sociology,
Atlanta, Georgia, USA

ABSTRACT

Autism spectrum disorder (ASD) affects 1 in 59 children and represent the fastest growing developmental disorder in the United States. However, disparities in ASD evaluation, diagnosis, and services exist based on social factors such as race, ethnicity, and socioeconomic status. To date, limited qualitative research has been conducted that focuses on the experiences of single black female caregivers of children with ASD who live in low-income, minority, and underserved communities in the United States. Objective: This study aimed to understand interrelated social and structural factors that place children and their families with limited resources at risk of delayed ASD diagnostic services and limited therapeutic services. Methods: The study design is based on in-depth interviews conducted with single black female caregivers of children with ASD who rely on state Medicaid health insurance in metro Atlanta, Georgia (N = 21). A grounded theory analysis of the interviews was used to systematically identify themes and multi-level barriers to ASD services. Results: Despite improvements over the past several decades in diagnosing children with ASD, this study identified multiple and interacting social, economic, and residential barriers to accessing ASD services. Two themes were identified that contextualize barriers to ASD services: bureaucratic processes and geographic location of services. These barriers were compounded by the consequences of being a single female parent, including having limited income, employment options, and social capital. Practical recommendations to break the cycle of ASD service disparities are discussed.

INTRODUCTION

Autism spectrum disorder (ASD) is defined by the American Psychiatric Association as a lifelong neurodevelopmental disorder characterized by persistent challenges in “social communication and social interaction,” and “restricted, repetitive patterns of behavior, interests, or activities” [1]. According to the Centers for Disease Control and Prevention (CDC), ASD affects 1 in 59 children and is the fastest growing developmental disorder in the United States [2]. Recommended treatment for ASD consists of early intensive behavioral and educational interventions [3]. A trained clinician can reliably diagnose ASD in children as early as 2 years old or younger, but most children are not diagnosed with ASD until after age 4 years [2].

ASD is prevalent in all racial and ethnic groups and across all socioeconomic levels; however, disparities exist in the prevalence of ASD associated with social factors, such as by age, sex, race, ethnicity, and geographic area [2]. For example, boys are four times more likely to be identified with ASD than girls [2]. In metropolitan Atlanta, Georgia, which consists of five counties, including Clayton, Cobb, DeKalb, Fulton, and Gwinnett, the prevalence of ASD for both white non-Hispanic and black non-Hispanic children increased from 1996 to 2010 [4]. However, disparities in prevalence of ASD remain evident between white children (18.1 per 1,000) compared to black children (14 per 1,000) diagnosed with ASD in 2010 [4].

In addition to ASD prevalence disparities, population-based quantitative studies have reported that a range of ASD diagnosis and service disparities are associated with race, ethnicity, and social class [5-9]. A quantitative analysis of Medicaid claims of 406 children in Philadelphia found that black children who received specialty mental health services through Medicaid received more time in treatment before obtaining an ASD diagnosis [5] and were 2.6 times less likely than white children to receive a diagnosis on their first specialty care visit [6]. One study that examined racial disparities in identification of ASD in metropolitan Atlanta found that black children were less likely to be identified with milder forms of ASD and more likely to receive the most severe diagnosis compared to white children [7]. Other studies found that there are ASD disparities associated with age of diagnosis, access to therapeutic services, and even racial representation in special education programs at schools [9-11]. Disparities in early evaluation and ASD diagnosis can significantly affect children with ASD and their families mainly because they delay access to early intervention, which is essential for improved developmental outcomes [11]. It is recommended that children with ASD receive twenty or more hours per week of behavioral intervention such as Applied Behavioral Analysis (ABA) therapy [12]. However, several studies have found that children with ASD who are from racial and ethnic minority populations and communities are less likely than white children with ASD to access publicly funded community-based services, including early intervention and ABA therapy, and those who do are less likely to receive the recommended intensity of twenty hours per week [12].

Although population-based quantitative studies offer important knowledge of factors associated with delays and/or barriers related to ASD diagnosis and services, this literature is relatively descriptive in nature and does not typically consider interrelated social or structural factors that place children and their families at risk of delayed assessment, diagnosis, and/or services [13]. Further, quantitative studies on ASD disparities have little to say about the

complex and multi-level challenges faced by caregivers in accessing services for their children after a diagnosis has been made. Knowledge gained from qualitative research offers a more nuanced and contextualized understanding of health disparities based on individual lived experiences situated within the context of social and structural dynamics through which health disparities arise and are sustained, reproduced, and perpetuated [13].

In contrast to quantitative ASD research, there is limited qualitative research based on the experiences of families living in low-income, minority, and underserved communities. A recent review conducted by the second author (JS) found that existing qualitative research on ASD disparities focused on the high cost of ASD services, and lack of competence and training in ASD diagnosis and interventions among healthcare and educational professionals [13]. The same study found limited qualitative research that examined structural inequities related to operations of systems of care and the regulatory and policy climate [13]. Research on the impacts of caring for a child with ASD in alternative family structures is also limited as well as the responsibility taken on by women in general, who are typically the primary caretakers of children, especially children with disabilities [13-14]. Further, the representation of female caregivers of children with ASD in the United States is often uneven, with most voices in qualitative research and mainstream culture being those of married, white, upper-class mothers who have the time, social capital, and financial resources to seek early diagnosis and acquire expertise and knowledge on how to help their children [13-15]. Our research was informed by these gaps in the existing literature on ASD disparities.

The purpose of this study was to investigate and identify structural inequities that are embedded in the process of navigating state Medicaid insurance for ASD services in Georgia. We define structural inequities as customs, practices, or laws that shape health disparities, including healthcare policies and state programs. Medicaid is a federal program that helps with medical costs for low-income individuals, but how it is designed, managed, and implemented differs from state-to-state [16]. There is a long history of the positive impact of Medicaid policy on statewide access to care for low-income and minority adults and children [17]. For example, reliance on Medicaid has been found to be associated with less out-of-pocket medical expenses and reduced financial burden on families [17]. However, an unequal distribution of Medicaid services exists across the United States (e.g., differences in Medicaid reimbursements for each state) and even within individual states (e.g., differences in county-level spending on education versus healthcare resources) [17-18]. Health insurance, including Medicaid, is one factor among many that has an impact on access to services and health outcomes. Thus, we focused on the compounding factors associated with accessing Medicaid ASD services for single black women who rely on state Medicaid insurance. More specifically, this study investigated the constraints of Medicaid that make it difficult for caregivers to access ASD services after children receive an ASD diagnosis.

Conceptually, this paper draws on a model (see Figure 1) adapted from the “Cycle of Environmental Health Disparities framework” that outlines the complex environmental interactions in health disparities by identifying a range of interrelated adverse environmental risk factors at the individual, residential, and community levels [19]. The “Cycle of Autism Disparities” (see Figure 1) centers on compounding factors (e.g., limited social capital and limited educational and healthcare services) since these factors are central to understanding ASD disparities among underserved communities. For our analysis, we focused on relationships between compounding factors, social and economic factors (e.g., limited education, empowerment, and income), and residential options (e.g., limited choice,

infrastructure, and services) portions of the cycle (circled in Figure 1). This model also offered entry points to further expand our understanding of different risk factors associated with ASD service barriers and areas for targeted recommendations to break the cycle of ASD service disparities, which we elaborate in the discussion.

Figure 1. Cycle of autism disparities.

OUR STUDY

This research was approved by Children's Healthcare of Atlanta, Georgia Institute of Technology, and Morehouse School of Medicine Institutional Review Boards, as well as the Grady Research Oversight Committee. Audio-recorded, in-depth interviews were conducted by the second author (JS) with single black female caregivers of children with ASD who rely on state Medicaid health insurance ($N = 21$). These interviews formed the basis of our analysis and were a subset sample of a larger project designed to assess the quality of care of a community-based Autism Clinic and identify barriers to ASD diagnosis and services ($N = 72$). Interviews were conducted with caregivers whose children received services at the Autism Clinic located in a non-profit children's hospital in Atlanta, Georgia, where most of the patients rely on Medicaid. Participants were asked open-ended questions about their experiences before, during, and after receiving a diagnosis. All interviews were recorded, transcribed, and uploaded in HyperRESEARCH, a qualitative data analysis software program [20]. All the participants were given a pseudonym in the presentation of our findings to protect their confidentiality.

This study used a grounded theory analysis of the interviews to systematically identify themes and multi-level barriers to ASD services [21]. This involved using HyperRESEARCH to code segments of qualitative data to specific categories and write detailed memos for categories to capture the data conceptually. Analysis began with open coding of words,

phrases, and passages in the interview transcripts. Open coding is an established analytic method used in studies guided by grounded theory methodology, whereby participants' responses are compared, and conceptual labels are defined in an iterative process [21]. The second author (JS) developed a preliminary codebook, which was refined as we inspected the data multiple times. The codebook was used to identify common themes shared by participants that reflected and further elaborated the Cycle of Autism Disparities framework (see Figure 1).

FINDINGS

The ability of single black female caregivers to access early intervention and appropriate services through Medicaid insurance after receiving an ASD diagnosis were often compromised due to multiple interacting factors apparent in the Cycle of Autism Disparities framework. Of the sample interviewed, all the study participants identified as black or African American, were single, either never married or divorced, and their children relied on state Medicaid insurance (see Table 1). Sixteen of the caregivers were mothers, and five were grandmothers. Fifty-seven percent of the caregivers were unemployed, thirty-eight percent did not have a college degree, eighty-five percent had a household income of less than \$30,000 a year. (Note: the federal poverty level for a four-person household in 2018 was \$25,100 [22]). Previous studies on ASD disparities have shown that lower income and/or parental education are associated with lower ASD prevalence, later diagnosis, and less utilization of ASD-related services [12]. Thus, the demographics alone place these women at higher risk of experiencing disparities in ASD services. Forty-three percent of the women in the sample also resided in the southern part of Fulton County, an area marked by limited healthcare resources, limited services in public schools, and lower median household income [23]. Relatedly, sixty-seven percent of the women in this sample rented an apartment or home or were living in temporary housing (e.g., shelters), and twenty-nine percent took care of more than one child diagnosed with ASD. As we will elaborate below, the interaction of these demographic characteristics is evident in the Cycle of Autism Disparities (see Figure 1), including how limited healthcare resources and educational services (Compounding Factors) available in southern Fulton County (Residential Options) interact with caregivers' educational attainment, income, and employment status (Social and Economic) and their ability to coordinate and access services for their children.

A unique feature about this sample was the fact that these families had access to initial evaluation and diagnosis, which was covered through Medicaid. Most of these families received initial evaluation and diagnosis at the Autism Clinic (69%), while others received initial diagnosis elsewhere (31%). Although access to early evaluation and diagnosis was not the focus of this analysis, caregivers in our sample expressed that "not knowing much about autism," complicated schedule coordination, and long waiting lists were the predominant barriers to early diagnosis. Despite improvements over the last few decades in diagnosing children from racial and ethnic minority communities with ASD in Atlanta, the women in this study continued to experience significant barriers when it came to accessing ASD services such as behavioral, speech, or occupational therapy [2]. Thus, their stories reveal how Medicaid served as an access point to obtain an ASD evaluation, diagnosis, and service

referrals, while at the same time Medicaid served as a barrier in accessing subsequent ASD services especially in certain geographical locations in metro Atlanta. Two themes were identified that contextualize Medicaid as a barrier to ASD services: bureaucratic processes and geographic location of services.

Table 1. Participant demographics (N = 21)

Demographic	Percent of Sample
African American or black	100%
Single Parent or Divorced	100%
Medicaid	100%
Unemployed	57%
Some High School/Diploma/Vocation	62%
Household Income <20K	52%
Household Income 20K – 30K	33%
Live in south Fulton County	43%
Rent Apartment / House or Temporary Housing	67%
More than one child diagnosed with ASD	29%

Bureaucratic Processes

It was clear from the stories told by these mothers and grandmothers (24% of sample) that difficulties in accessing services for their children can be contextualized by the complex and often confusing bureaucracy of acquiring ASD services in Georgia. Many caregivers in our sample voiced their confusion and frustration regarding how Medicaid did not cover some of the recommended services for their children or only covered services for a short period of time. Navigating bureaucratic systems is even more difficult because requests for services are lengthy to process, which can result in delays or long waits for caregivers to acquire the appropriate services for their children. Chantel, the mother of a ten-year-old child diagnosed with ASD and another nine-year-old child who displayed developmental delays and behavioral issues, was no stranger to lengthy wait times and limited services available through Medicaid. After being referred to the Autism Clinic for an initial ASD evaluation, it took almost a year for her to secure an appointment for her older child. It was at this first appointment that this child received a diagnosis of ASD. As part of his recommended treatment, Chantel's ten-year-old child did occupational therapy at a rehabilitation center for three months. Although she found occupational therapy helpful for her child in improving his fine motor skills, she ultimately had to discontinue the therapy after Medicaid stopped covering it after three months. At the time of the interview, Chantel had also been looking for a speech therapist for over a year that accepted Medicaid near her home in south Fulton County. Traveling far distances was not a practical option either because Chantel also had to take care of her younger, nine-year-old child who was scheduled to be evaluated for ASD. Chantel was further discouraged by her inability to follow up on referrals received at subsequent appointments for her ten-year-old son because those referrals "did not take Medicaid."

Another young single mother from south Fulton County named Tianna echoed Chantel's sentiments and had difficulties finding an occupational therapist who would accept Medicaid for her five-year-old son diagnosed with ASD. Tianna was the mother of four children and worked full-time as a janitor. Tianna was frustrated because the Medicaid referrals she received from the Autism Clinic were booked and did not have a wait list. As she explained,

"When I called to schedule an appointment, they said they were booked. There was no waiting list, and they didn't have anyone who could see him because I wanted later hours."

Even though there are other private therapy options available outside Medicaid—which were often located farther away in the northern part of metro Atlanta—Chantel and Tianna could not afford them, and even if they could afford the out-of-pocket cost of these services, they would have to sacrifice their work hours or attention given to their other children. These examples illustrate how limited health care services (Compounding Factors), single parenthood and limited income (Social and Economic), and location of residence (Residential Options) interact with one another in the Cycle of Autism Disparities.

The bureaucratic limitations of Medicaid are compounded when additional institutions are involved. Children with ASD have needs that straddle both healthcare and educational systems. Special educational services for children with ASD are mandated under the Individuals with Disabilities Education Act (IDEA), a federal law that requires a free and appropriate public education be available to children with disabilities in defined age ranges [24]. An Individualized Education Program (IEP), which includes a full evaluation of the child with regards to development, speech, or attention, is required for most children to be eligible for services under IDEA in order to receive special education services in public schools [24]. Several caregivers in this study discussed their frustrations with the bureaucratic process required to receive or change an IEP. Sasha, for example, was the mother of a teenaged daughter diagnosed with ASD. Sasha and her three children relocated to Atlanta from North Carolina and at the time of the interview, she was unemployed, financially dependent on her oldest child's income, and lived in a shelter in south Fulton County. Although Sasha first became concerned with her daughter's development when she was an infant, her daughter did not receive a diagnosis of ASD until she was in the sixth grade (when she was around ten years old), at which time Sasha tried to change her daughter's IEP. Due to the time it took to process the necessary paperwork to amend the IEP, Sasha was not able to get her daughter in the "right class" until she started the seventh grade:

"I had to wait until she graduated sixth grade even though she had a diagnosis of autism."

Sasha went on to say how difficult it was to change her daughter's IEP from a "behavioral intervention class to an autism class," which Sasha believed was more appropriate because the class focused on autism and therefore potentially more beneficial for her daughter.

Another caregiver pointed out an additional complication regarding bureaucratic processes: the educational and medical systems often did not align when it came to

evaluations. This caregiver was the mother of six children, and three of her children were diagnosed with ASD. As this mother elaborated,

“Yeah, [the school] bases [the IEP] on their school system evaluation and not the medical records. Not the doctor’s notes. Nothing dealing with your doctor. You may have a child that has autism or other behavior issues that needs to be in a smaller-setting classroom, but when [the school] tests them, and it’s not to their liking...Dealing with the school system is like dealing with a whole another government. They have their own set of rules, and personally, you know, for me, I think it’s hurting the child to be honest.”

These narratives highlight the complicated bureaucratic processes embedded with both the medical and educational public systems and how navigation of these processes for single women with limited resources shape disparities to ASD services.

Geographic Location of Services

Another salient and recurring theme is how geographic location of services was identified as a constraint to obtaining ASD services. For example, let us consider the experiences of Cynthia, a parent of three children diagnosed with ASD. She resided in south Fulton County, the father of the children was not involved, and she had limited social support from other family members. Alongside the bureaucratic frustrations that came with trying to secure healthcare for her children, Cynthia was frustrated about the limitations of Medicaid coverage and the lack of services around where she lived. Cynthia felt her options were limited because her children were reliant on Medicaid and noted that “there are not many doctors, medical professionals that take the Medicaid.” When asked about her biggest challenges in accessing behavioral therapy for her children, Cynthia answered:

“Well, I can say the area I live... [and] the locations of some of the places that offer the services are...not in my local area, so I have to drive a great distance to get the services. So that’s the biggest challenge. There’s nothing in my area within a twenty-mile radius, so I have to drive to get there.”

Cynthia fortunately had access to the use of a car, which helped her reach therapies that were more than twenty miles away. However, for many of the women in this study, transportation served as a challenge because they relied on public transportation or Medicaid transportation, both of which were not always reliable or practical given these women’s demanding life schedules. Caregivers who utilized Medicaid transportation noted that the van was often time-consuming and unreliable. One mother described an incident where she had to reschedule an appointment for her daughter because the Medicaid van was delayed in picking them up. Another mother noted how she found herself late to several appointments at the Autism Clinic because the van often serviced multiple people:

“You’re not the only one riding that van. They have other clients, other customers they have to pick up, as well as pick you up and drop you off. So, you have to sometimes wait until they pick up those guys, and you might be the second or third or fourth person being dropped off...And sometimes, you might be the last person to get dropped off.”

In addition, the services these women needed to access for their children were often not easily accessible by public transportation. One grandmother, Karen, who resided in south

Fulton County expressed how she was unable to take her three-year-old grandchild diagnosed with ASD to an afterschool learning center that provided services to help children with developmental disabilities:

“A lot of places are too far. We have no way of getting there. Because of transportation issues...Some of the places are just too far and off the bus line, and I don’t have a vehicle, so it makes it harder for me, you know.”

At the time of the interview, Karen was recovering from a stroke which she attributed to stress experienced from raising her grandchildren in addition to her own eleven-year-old daughter. Karen was also in the process of adopting her three-year-old grandchild (as well as two other grandchildren who were not diagnosed with ASD). Karen’s frustration with transportation issues was felt by parents who owned or had access to a car, but it was heightened for those who had to rely on public transportation.

Figure 2. Behavioral therapy services in and around Fulton County.

To add insight into the structural inequities in ASD services in metro Atlanta, a representation of how ASD services are unequally distributed based on geographical location is depicted in Figure 2. The map shows a sample of the places that offer behavioral therapy for ASD. As the map illustrates, there is a lack of behavioral therapy service sites in southern Atlanta, such as south Fulton County (shaded in darker grey area at the bottom in Figure 2) where Cynthia and forty-three percent of the women in this study live. Those sites that offer behavioral therapy were also often difficult to access with public transportation, and not all of the sites represented in Figure 2 accept state Medicaid insurance. The lengthy travel time to therapies further compound the recommended hours of behavioral therapy per week, which is recommended at more than twenty hours per week [12]. In addition, managing work and family life balance for caregivers could be especially challenging if children receive multiple therapies and/or have other healthcare needs in addition to ASD or if parents take care of more than one child with ASD (six parents in our sample had more than one child diagnosed with ASD).

Compounding Factors

The challenges associated with both the complex bureaucracy and limited location of services are compounded with other factors evident in Cycle of Autism Disparities framework (see Figure 1). First, these women's challenges were complicated by limited employment options, low income, and stressful environments they and their families must navigate on a daily basis. For example, having to rely on public transportation with a child diagnosed with ASD compounds the challenges these women experience while navigating ASD services. Some of the women told stories of how public transportation created environments that were often difficult for their children to handle due to strange smells, loud noises, large crowds, and long wait times. Sheila, a single black mother who just moved to Atlanta with her teenaged daughters, reflected on how she and her fifteen-year-old daughter diagnosed with ASD could not reach their appointments because her daughter refused to take public transportation,

"Sometimes I was having trouble with her getting on the train and on the bus...Sometimes she doesn't want to ride. Since the doctor has been helping with the medicine, it's not as bad as before. Before, I couldn't even take her on the bus when there was a whole bunch of people. Because she would have episodes, or she thought people were staring at her."

Also complicating access to care were the barriers related to the consequences of being a single parent, which for this sample was related to navigating ASD services with limited resources and reliance on state services like those supported by Medicaid. Sasha, the previously mentioned mother who encountered problems changing her daughter's IEP, described the difficulties of being a single parent who cares for a child with ASD alongside the multiple responsibilities she faces:

"If you have a child that has a disability it's even more pressure on me because it's like I have to be Superwoman for everybody else. I still have to deal with regular stuff and on top of regular stuff, deal with other stuff. Sometimes it's kind of overwhelming when you don't have that partner there to help you...I have to go every place to take to her therapist appointment, her speech appointment. I have to go to her school for IEPs, you know. I have to do a lot...My other daughter who's younger than her, she still has stuff I have to do with her for her school...Then my oldest daughter, even though she's twenty-seven, I still have to be her momma to her too because she has things that's going on in her job."

Additionally, in many cases parents of children with ASD may find their ability to work during their designated employed work hours periodically constrained, which can be especially challenging for single parents [25]. For example, Janice, a full-time nursing assistant and the mother of a four-year-old child diagnosed with ASD, was asked to leave her previous job due to the demands of taking care of a child and the toll it took on her work life:

"I made a lot of sacrifices. My other job, I really loved my other job, but I had to leave it due to me leaving work early. Like, if [my child] has a big meltdown, nobody could control him, so I had to leave work and go see him. My supervisor sat me down, and she was like, "You've been taking a lot of days off." I told her what was going on, but she said, "You can stay, or you can leave." I had to leave because this is my son, and I left that company. You know, I really loved that company, but I'm the care provider, I'm his mom, I'm his only parent, and I don't want to ever feel like I'm neglecting him because I'm trying to go to work."

This compelling statement highlights the negotiations that single working women have to contemplate to meet the needs of their child with ASD and the limits on what they can do in their jobs and lives. This caregiver, like many others, must balance the needs of her child with a desirable job, not to mention a job that she needs to support her son. Unfortunately, Janice's employer did not offer the flexibility she needed to manage being the primary breadwinner *and* the primary caregiver. These are conflicts single female caregivers must face, which is compounded when caring for a child with special healthcare needs.

Though this paper focused on the shortcomings of autism services offered through public medical and educational systems, several of the women interviewed were able to quickly acquire services for their children with little difficulty. These women often had financial and/or social support from the fathers of their children or other family members. Some women had the education and knowledge resources to navigate different and equally complex bureaucratic systems. For example, Janice had a bachelor's degree and due to her job as a nursing assistant, had extensive knowledge about Medicaid services and how to acquire various therapies for her son. Janice also sought help and information from a coordinator at the Autism Clinic to arrange multiple therapies for her son. Unlike many of the women in our sample, Janice was able to have her child access several different types of therapies and activities through Medicaid, including speech therapy, occupational therapy, physical therapy, swimming lessons, and soccer. These alternative experiences within the sample highlights the heterogeneity of the population under investigation and the importance of having different forms of empowerment and social capital among caregivers in order to navigate complex bureaucratic systems of care. Though public medical and educational programs have enhanced and improved the ability of disadvantaged populations to receive healthcare and related services, ultimately there continues to be areas for improvement.

DISCUSSION

These narratives of single black women negotiating ASD services in metropolitan Atlanta offer firsthand accounts of frustrations that caregivers encounter in dealing with multiple bureaucratic systems of care. These results are in line with a body of research that suggests that when multiple systems are responsible for providing related services to the same child, it can result in considerable gaps and inefficiencies in care [18]. The fragmented systems of care and the amount of work required to gain access to state programs and special education services are constraints that are compounded for low-income single, black, female caregivers who are typically doing all the care coordination with limited assistance and/or resources. One avenue to break the cycle of ASD disparities is to consider how medical and educational state programs can work together in offering complementary services for complex conditions like ASD. For example, some researchers have made the case that social workers and occupational therapists who have contact with families of young children might support in early identification and appropriate referrals [26-27]. Another study found that increased school district funding was correlated with higher proportions of children identified with ASD in schools [28]. Because schools play an important role in identifying children with ASD and other developmental disorders, allocating financial resources and personnel trained

to identify ASD to schools in economically disadvantaged communities may help alleviate ASD disparities [28].

Expanding the location of ASD services also points to areas where we can break the cycle of ASD disparities. The experiences of these families who live in south Fulton County highlight how Residential Options (e.g., limited healthcare services in geographic area) and a range of Social and Economic Factors as indicated above. These interrelated factors also matter with regards to race and social class. For example, according to data generated by the US Census, the racial demographics and median household income in Fulton County are starkly different for north Fulton and south Fulton County. For example, in the East Point subdivision of south Fulton County, Blacks account for 79.1 percent of the population, and the median household income was \$35,974 in 2010 [23]. By contrast in the Roswell-Alpharetta subdivision of north Fulton County, blacks made up only 12 percent of the population (whites composed 61.6 percent of the population here), and the median household income was \$97,291 in 2010 [23]. We know that higher socioeconomic status (SES) correlates with higher ASD prevalence estimates [29]. However, less is known about the effects of compounding factors like living in a lower SES neighborhood that is racially divided. Our data suggests that these are important areas for further investigation. Previous research by Mandell et al. [18] have found that differences in local policies, practices, and resources could result in variation in which children with ASD receive care in the Medicaid system. In our study, difficulties in accessing services can be further contextualized by the lack of services around where these women live and lack of access to reliable transportation if services are farther away. Thus, in addition to addressing the limited ASD services available in low-income and underserved communities, such services should also be made available close to public transportation lines and/or offer transportation services as part of the therapy. The creation of therapy clinics that offer multiple ASD services in one place may also eliminate the constraints placed on caregivers who must travel to multiple locations to acquire different therapies for their children.

As evident by these narratives, the intersecting constraints of trying to access ASD services as a single parent with limited resources highlight how various elements of the Cycle of Autism Disparities framework interact with one another. Several scholars have written about how the accumulation of demands has more consequential effects on populations who have fewer resources to manage their children's ASD [13]. For the women in this study, the knowledge, time, and energy necessary to navigate ASD services were compounded by the various challenges related to being a single parent. For example, single parents carry the burden of both unwaged and waged labor [30-31]. In this case the unwaged labor consists of navigating the bureaucratic processes needed to obtain ASD services in addition all the other caregiving work required to raise a child with special needs. Previous research also found that achieving and maintaining employment was more difficult for parents of children with disabilities than for those without children or without children with disabilities [25, 32]. Cidav et al. [32] found that mothers of children with ASD earn fifty-six percent (\$14,755) less than mothers of children with no health limitations, and they are less likely to be employed and work seven hours less per week, on average, than mothers of children with no health limitations. Given the substantial healthcare expenses associated with ASD, the economic impact of having lower income in addition to these expenses is magnified for caregivers of children with ASD [32].

The intersections of gender and race also matter when considering ASD disparities, especially with regards to income inequalities. For example, various studies have shown there are economic sources of inequity due to persistent gender and race differences with regards to types of work that women do and the income they receive [33-34]. It was found that irrespective of the level of qualification, jobs predominantly done by women pay less on average than jobs predominantly done by men [33]. According to a Pew Research Center analysis of median hourly earnings of both full- and part-time workers in the United States, women earned eighty-three percent of what men earned in 2015 [34]. This same study also found that the hourly earnings of black and Hispanic women (\$13 and \$12, respectively) are lower than those of Asian and white women (\$18 and \$17, respectively) [34]. Our analysis highlights how the challenges of raising a child with ASD was magnified by having limited income, employment options, and social capital (access to knowledge and resources based on one's position in society). These multiple and interrelated factors compounded the difficulties these women experienced in accessing ASD services for their children. While Medicaid coverage lowers financial barriers to accessing healthcare services for low-income uninsured people and improves their health outcomes, the stories these women tell highlight that the program can be further strengthened by addressing recognized shortcomings.

Avenues to break the cycle of ASD disparities must consider these complex and intersecting factors when considering areas of intervention. For example, the development of patient navigation systems designed to provide lay case management specially for families with limited resources early on in ASD evaluation, diagnosis, and services can increase parent empowerment [35]. Such programs can be specifically tailored to address issues more apparent for single parent families, such as lack of social support, time, and job flexibility. ASD service disparities among black communities may also benefit from adaption of culturally tailored ASD interventions like the *promotora de salud* model, or community health worker model, to break the cycle for these communities [36]. The *promotora de salud* model uses a lay health educator from the target community who provides health information to other people in the target community after receiving training in the health topic [36]. For the caregivers of children with ASD in our sample, those with experiences of being single, black, female, and reliant on Medicaid would be the most qualified people to recognize areas of need and areas of strength. For example, a pilot study of parent training for Latinx mothers of children with ASD based on the *promotora de salud* model found that mothers reported improvements in their understanding of ASD, their child's strengths and needs, and how to help their child develop and learn, and knowledge of their child's rights [36]. In addition, the study reported that mothers felt improvements in having support systems, accessing the community and using evidence-based approaches efficiently to enhance social communication skills and manage behaviors for children with ASD [36]. These suggestions and others can be integrated in community-based settings like preschool and elementary school settings [37-38]. Our study supports that it is important to address not only system-level approaches but also the heterogeneity of barriers experienced by under-resourced caregivers of children with ASD [39]. Building social capital through such interventions offers important access points to knowledge, resources, and confidence that parents need to break the cycle of ASD service disparities.

CONCLUSION

The examination of ASD disparities in metro Atlanta provides a lens to a bigger problem regarding lack of services in urban areas that are divided based on racial and social class lines. However, the complex bureaucratic processes, lack of services based on geographic location, and interacting compounding factors are also not unique to ASD. People with other disabilities, chronic health problems, and anyone who relies on Medicaid or other state services often face similar challenges. This research focused on the experiences of single black women, whose ability to seek early intervention and appropriate ASD services were often compromised due to multiple compounding factors in a structurally uneven society. The firsthand accounts of the women in this study point to how different processes (Compounding, Social and Economic, and Residential Options) overlap and are contingent on each other. For example, limited health care services are tied to where people live and the choices available for seeking and accessing services. These women's narratives also add more nuance to the Cycle of Autism Disparities such as the effects of family structure (single parenthood, multiple children with special healthcare needs), the ability to balance work/family life (job flexibility), and transportation options (time, cost, practical considerations)—nuance that opens up and identifies new areas of research and intervention on how to break the cycle of ASD service disparities.

Recent and upcoming changes to Medicaid in the state of Georgia provide avenues for further research as well. In July 2017, the state of Georgia approved a mandate that made it a requirement for Medicaid to cover Adaptive Behavioral Services (ABS) to assess and treat ASD [40]. ABS include behavioral therapy and social skills development, and this policy was designed to improve outcomes for ASD. Because nearly half of the women in the sample for this study were interviewed before this mandate was put into effect, the impacts of this mandate currently remain unknown. One research avenue should investigate whether this mandate improves access to ABS and/or increases (or decreases) the bureaucratic processes needed to access these types of ASD services. Further, would such a mandate increase the number of behavioral services in underserved urban areas? The expansion of Medicaid in Georgia through the Patient Protection and Affordable Care Act also holds potential for recipients of Medicaid [41]. However, since minorities and women are disproportionately more likely to utilize social assistance programs like Medicaid, these programs are politically vulnerable. As such, recipients are particularly likely to be affected by budget cuts and shoulder the various hardships that accompany reliance on such programs [30-31]. Recently in 2019 the Georgia Legislature approved a plan to expand Medicaid, albeit on a limited basis [42-43]. There is value in studying the ramifications of Medicaid expansion on healthcare outcomes for low-income, minority, and underserved communities in Georgia. It remains unknown if the limited expansion Medicaid would address the concerns voiced by the women in this study. There is much value in taking note of how recent and upcoming changes to Medicaid in the state of Georgia would affect ASD disparities.

At the individual level, we also have much to learn from the personal stories of the female caregivers themselves, as they provided recommendations to address some of the daily challenges they faced and practical ideas on how to break the cycle of ASD disparities. One recommendation from a mother who worked full-time and could not find an occupational therapist close to her home that accepted Medicaid suggested the integration of Mobile

Therapy Units that accept Medicaid in areas like south Fulton County. Such easily transportable therapy services would address the problems related to geographic location of services, as well as create options for offering services in the evenings and/or weekends, when working parents are more likely to be available. One parent voiced her concern that community support groups tended to meet up in Gwinnett or north Fulton County, which are more than twenty miles away and not easily accessible by public transportation. Her suggestion was to create community support groups in south Atlanta that were close to public transportation. Southside Support, a community support group based in south Atlanta, was started recently in response to this need [44].

Offering childcare during these sessions (as well as initial therapy sessions) would also allow parents the opportunity to fully engage in these important social support networks. These practical suggestions offer important starting points in breaking the cycle of ASD disparities that may help to alleviate the daunting and often overwhelming task of navigating ASD services among single black women in this study, as well as other families and communities who are situated in similar interacting cycles of health disparities.

ACKNOWLEDGMENTS

This work was supported by Break the Cycle of Environmental Health Disparities 14 and the School of History and Sociology at Georgia Institute of Technology. We would also like to express our gratitude to Dr. Leslie Rubin, the Break the Cycle staff and faculty, and all the women in this study who contributed their valuable time and energy to telling their stories about navigating ASD services.

ABSTRACT

Autism spectrum disorder (ASD) is a developmental disability characterized by significant social, communication, and behavioral challenges. Early diagnosis and treatment have shown to improve health outcomes. ASD diagnosis can be achieved by age 2 years, but median age of diagnosis is 4-5 years. The purpose of this project is to identify barriers and facilitators to ASD diagnosis and treatment for families living in rural or Medically Underserved Areas (MUAs). Methods: Two focus groups were conducted online and in-person with parents of children with ASD living in rural and MUAs. Questions examined health disparities and delayed diagnosis or treatment. Sessions were audio-recorded, transcribed, and analyzed. Results: Diagnosis and treatment barriers included distance to healthcare services, limited access to providers, inadequate insurance coverage, and lack of education. Facilitators included school referrals, research studies, ASD research centers, support groups, school-based treatments, and insurance extenders. Analysis revealed decreased parental autonomy, frustration, disappointment, uncertainty, and desire for support. Discussion: Parents of children with ASD living in rural and MUAs discussed several barriers to ASD diagnosis and treatment. Parent-identified ways to improve barriers included increased education,

* Corresponding Author's Email: ablumli@emory.edu.

enhanced awareness of ASD and needs of rural and MUAs, and improved access to care. Proposed interventions included telehealth and mobile clinics. Conclusion: Families living in rural and MUAs face many barriers related to ASD diagnosis and treatment. Future interventions should address these issues by increasing awareness of ASD, increasing knowledgeable providers, and utilizing electronic technologies to engage individuals in these areas.

INTRODUCTION

Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder characterized by communication, social, and behavioral challenges for affected individuals [1]. ASD is associated with a variety of both personal and family-level challenges, including the need for lifelong support and interventions. Families of children with ASD living in rural or medically underserved areas (MUAs) face additional challenges in obtaining a diagnosis and securing ongoing treatment due to a variety of factors, which results in potential healthcare disparities present in these populations [2-4]. There is currently a scarcity of research on families of children with ASD living in rural and MUAs and the role that disparities in services plays in the diagnosis and treatment of ASD. Therefore, the purpose of this project was to identify barriers and facilitators to ASD diagnosis and treatment for families living in rural or MUAs.

AUTISM SPECTRUM DISORDER

Symptoms of ASD emerge in early childhood and include difficulty with communication, difficulty with social-emotional reciprocity, and the presence of restrictive and repetitive behaviors or interests [1]. The current prevalence of ASD is estimated to affect 1 in 59 children [5]. In addition to the primary characteristics of ASD, children with ASD encounter numerous health and behavioral comorbidities (e.g., seizures, gastrointestinal disorders, attention-deficit/hyperactivity disorder [ADHD], sleep disorders), increasing the complex needs of these children [5, 6]. Treatment for ASD includes evidence-based treatments, such as applied behavioral analysis (ABA) therapy, speech language pathology (SLP), occupational therapy (OT), and physical therapy (PT). As a result of the complex nature of ASD and its associated treatment, the lifetime cost of supporting a single individual with ASD in the United States is estimated to be between \$1.4-2.4 million [7]. Despite this costly economic burden on individuals and families, evidence has shown that early diagnosis and intervention for children with ASD can improve long-term health outcomes [7-10].

Given that signs and symptoms of ASD appear in the first year of life, clinicians are currently able to make a valid diagnosis as early as two years of age [1]. According to emerging literature, this age may actually be sooner for some children with ASD. [5, 8, 9, 11]. Despite these facts, the current median age that children receive an ASD diagnosis is between 4-5 years [2, 5, 8-10]. This delay in ASD diagnosis delays the child's ability to receive treatment services, resulting in a significant lag between presentation of symptoms and onset of intervention. This delay has great potential to negatively impact the developmental trajectory of the child, as it occurs during a critical time of early brain development [8-11].

Evidence has shown that a timely ASD diagnosis, coupled with early intervention, increases the likelihood of favorable long-term health outcomes [8, 9, 11].

Rural and Medically Underserved Areas (MUAs)

Geographic health disparities are associated with individuals living in rural or MUAs, where access to care affects their ability to receive necessary healthcare treatments. The United States Health Resources and Service Administration (HRSA) defines rural areas as those that have fewer than 2,500 people [12]. MUAs are defined as areas that have too few primary care providers, high infant mortality, high poverty, and/or a high elderly population [13, 14]. While limited access to healthcare services in rural areas may appear evident, often overlooked are those residing in MUAs who face even higher health adversities and disadvantages given their unique disparities. Research has found that individuals who are part of disadvantaged populations (e.g., geographic, socioeconomic, racial, ethnic) experience comparatively poorer outcomes in health [15-17]. Thus, delayed diagnosis and treatment of any health-related problem are more detrimental to the health outcomes of these disadvantaged populations [2-4, 17-20].

It is currently estimated that nearly one in five Americans live in rural areas and often struggle to meet their healthcare needs due to a lack of providers [21]. As of 2018, there were a total of 4,118 primary care health professional shortage areas identified in rural locations compared to only 1,960 in urban locations, thus increasing the vulnerability of these populations, as they are considered to be both medically underserved and living in a rural area [21]. As a result, life expectancy rates can vary by up to 20 years based on an individual's geographic location [16, 22]. At present, Georgia ranks in the lowest quartile in terms of life expectancy by state [16, 22], where nearly 90% of Georgia counties are designated as rural or MUAs (see Figure 1).

Figure 1. Map of medically underserved areas by county in the state of Georgia.

Cycle of Children's Health Disparities

Health disparities are present in children and families who have limited financial, social, medical, therapeutic, and educational resources. These disparities can be viewed in an intergenerational cycle that includes various geographic, health, environmental, personal, compound risk factors, and environments that can negatively impact a child's health (see Figure 2) [23-28]. This project aims to break the cycle of children's health disparities by exploring factors that impact families of children with ASD living in rural or MUAs, as indicated by the asterisks in Figure 2. As a result of this investigation, we intend to propose strategies to improve the health of children and families (see Figure 2).

Figure 2. Breaking the cycle of autism health disparities in rural and MUAs.

OUR STUDY

The principal study investigators recruited parents of children with ASD living in rural and MUAs of Georgia to explore barriers and facilitators to ASD diagnosis and treatment. The study was deemed exempt by the Emory University Institutional Review Board (IRB). Recruitment took place through flyers sent to local and rural pediatric clinics, social media support groups, and collaborative partners (e.g., Marcus Autism Center, Emory Autism Center, Department of Education Parent Mentors). Two focus groups were held, one in person and one online using remote, Health Insurance Portability and Accountability Act of 1996 (HIPAA)-compliant video-conferencing technology (i.e., Zoom) [29]. The two groups consisted of three to ten participants each, and they included parents of children with ASD and an additional stakeholder, the director of a special education school.

Focus groups utilized open- and closed-ended questions to identify potential barriers and facilitators to delayed ASD diagnosis and treatment. Questions also explored family-centered solutions to mitigate any potential disparities (see Table 1). The focus groups were audio recorded, transcribed, and analyzed using thematic analysis.

Table 1. Focus group guide

Focus group questions
1. Do you think there are any barriers or facilitators to receiving your child’s ASD diagnosis?
2. Tell me more about these barriers or facilitators.
3. Do you think there are any barriers or facilitators to receiving treatment for your child?
4. Tell me more about these barriers or facilitators.
5. What do you think should be done to help families get an earlier diagnosis or treatment?

FINDINGS

Participants represented numerous counties throughout the state of Georgia, some of which were up to 200 miles apart. Because of the interest from counties that were dispersed throughout the state, researchers decided to employ an innovative method for conducting qualitative research: utilizing both in-person and online videoconference focus groups. During the focus groups, participants discussed their perceptions of barriers and facilitators to early ASD diagnosis and treatment.

Figure 3. Georgia county map of interested participants.

Geographic Diversity

Initial participant recruitment resulted in high interest from a variety of geographically diverse locations throughout the state of Georgia. Interested participants spanned nine different counties dispersed throughout Georgia, including Walton, Troup, Fayette, Liberty, Bulloch, Sumter, Columbia, Henry, and Appling Counties (see Figure 3). The geographic diversity and distance in the sample compelled the researchers to conduct one of the focus groups online. This offered participants in a variety of counties a chance to have their voices heard in this study, despite the fact that their distant geographic location would have normally precluded them from participating in traditional in-person focus groups.

Diagnosis

Barriers and facilitators to ASD diagnosis were among the most frequently discussed topics during the focus groups. Parents living in rural and MUAs in Georgia felt that their experiences in receiving an ASD diagnosis differed from individuals living in more heavily populated areas, or areas with more providers.

Barriers

Parents described their journey to receiving an ASD diagnosis as being filled with various barriers that ultimately created a great burden to their family. The main barriers identified were distance to health care providers, provider shortages, inadequate insurance coverage, lengthy wait times, lack of parental and provider education on ASD, and limited ASD awareness of providers (see Table 2). Parents discussed problems with their initial concerns being dismissed by providers, lengthy wait times to see providers capable of making an ASD diagnosis, and limited providers working in their native counties. They also expressed frustration and disappointment in finding a lack of education and awareness about their child’s developmental concerns. Numerous concerns with insurance arose that impeded a child’s ability to receive a timely diagnosis, specifically providers capable of making an

Table 2. List of barriers and facilitators to ASD diagnosis and treatment

	Barriers	Facilitators
Diagnosis	- Distance to health care providers - Provider shortages - Inadequate insurance coverage - Lengthy wait times for providers - Lack of parental and provider education on ASD signs and symptoms - Limited ASD awareness of providers	- School system referrals - Working with ASD research centers - Participating in research studies
Treatment	- Distance to health care providers - Limited providers in immediate area - Inadequate insurance coverage - Cost of treatments - Competing time demands - Lack of follow-up plans for the child	- Social media support groups - Insurance extenders - Access to school-based treatments

ASD diagnosis not accepting certain insurance. Limited providers in the area, combined with dissatisfaction with the available providers, led many parents to seek providers outside their immediate counties. This often required them to travel upwards of two hours roundtrip for a single appointment to discuss their child's signs and symptoms.

Quotes from Parents Related to Diagnosis Barriers

The following quotes from parents represent the variety of barriers that parents living in rural or MUAs in Southern Georgia face in pursuance of an ASD diagnosis for their child:

Lack of ASD Awareness – Participant 1: "...They just kept telling me that my kid's lazy, that boys are lazy, and that's what I was being told the whole time."

Limited Providers & Lengthy Wait Times – Participant 2: "...There is nowhere around here that I knew of, or that at the time, my pediatrician knew of... that could give the autism diagnosis other than [large autism centers], [both] of which at the time was on an extremely long waiting list."

Facilitators

Although parent participants heavily emphasized the barriers to early diagnosis, they also discussed some facilitators that helped the process of diagnosis (see Table 2). Facilitators to diagnosis included school system referrals, working with large ASD centers, and participating in research studies. Parents felt that these facilitators improved early diagnoses. Examples of how these processes facilitated an earlier diagnosis included educators having a developmental concern for a child and making a school-based referral, having access to large ASD centers where professionals are specifically trained in ASD diagnosis and treatment, and opportunities for parents to have their child in research studies that provided ASD diagnosis and/or treatment (e.g., studies that evaluate siblings of children with ASD for developmental delays). Additionally, parents mentioned that their own persistence and determination in pursuing a diagnosis for their child were the most influential facilitators.

Quote from Parent Related to Diagnosis Facilitators

The following quote from a parent represents the facilitators that aided parents in receiving an ASD diagnosis for their child in rural and MUAs:

Parental Perseverance – Participant 3: "...Most of the parents here, we're the go-getters, we're the advocates. I had learned at an early, younger year, like, I have to fight, fight, fight and not take 'no' [as an answer]..."

Treatment Services

Upon receiving an ASD diagnosis, parents discussed factors that impacted receiving treatment services for their child. Accessing follow-up care after the ASD diagnosis and receiving ongoing treatment were often problematic for parents living in rural and MUAs.

Barriers

When identifying barriers to ASD treatments for their child, parents discussed many of the same problems associated with barriers to diagnosis (see Table 2). These treatment barriers included distance, limited providers, insurance, cost, competing demands, and lack of follow-up. Similar to diagnosis barriers, treatment barriers centered around the lack of

providers in the immediate area who were able or willing to provide ongoing treatments to children with ASD. Parents also mentioned that the state-wide early intervention programs were not necessarily helpful, as there appeared to be a severe provider shortage for these programs in their rural and MUAs. Of the limited providers available, parents often mentioned that they once again had problems with providers taking certain types of insurance for the treatments. When insurance was unwilling to cover these expenditures, it caused parents to pay out-of-pocket for often expensive interventions. This led to parents seeking providers outside their native counties who would be willing to treat children with ASD, as well as accept their insurance. This ultimately led to problems with competing demands requiring extended time commitments, such as missed school or work days.

Finally, a large problem identified was the lack of follow-up care for parents once they received an ASD diagnosis for their child. Parents expressed that they were relieved once they received the ASD diagnosis, but then felt unsure as to how they were supposed to follow-up or with whom in their native counties for treatment services. Parents described a lack of coordination and clear direction for parents regarding treatments, services, or facilities to seek out after receiving their child's ASD diagnosis.

Quotes from Parents Related to Treatment Barriers

The following quotes from parents represent the barriers to treatment and follow-up care for their child with ASD in rural and MUAs in Georgia:

Limited Providers – Participant 4: “Two different problems...Getting the diagnosis, but then even when you get the diagnosis, that doesn't solve everything [because] then there's not [any] treatments [in rural areas].”

Distance – Participant 5: “I have to drive an hour east or two hours west to go to an appointment. So, he misses school, and it happens because we live in a rural area.”

Lack of Follow-Up – Participant 1: “I thought...I was there getting a diagnosis and you're going to help me fix him. And I remember saying, ‘well, what next?’”

Facilitators

Aside from the overwhelming barriers to accessing evidence-based treatments, parents identified certain facilitators that enhanced this process (see Table 2). Social media support groups (e.g., Facebook), insurance extenders and access to school-based treatments were identified as facilitators to ASD treatment. Social media groups allowed them to find both helpful resources and support for their experiences. Parents expressed that these social groups helped with the processes involved in applying for services, such as specific treatments or insurance extenders. The insurance extenders, or medical Deeming Waivers (previously known as the Katie Beckett Waiver) [30], allowed families of children with disabilities to apply for Medicaid coverage services without their family income being taken into consideration. Lastly, school-based therapies or school systems that offered evidence-based therapies were found to be facilitators to treatment. Unfortunately, few school systems in Southern Georgia were reported to offer such services.

Quotes from Parents Related to Treatment Facilitators

The following quotes from parents demonstrate how social media support groups and insurance extenders facilitated treatment for their children:

Social Groups & Insurance Extenders – Participant 3: “...[Social media groups] ... had people talking about the Katie Beckett and trying to...apply for the Katie Beckett was very overwhelming, frustrating. So, they said, you know, hey, there's a specific group that helps you, that does that, so you can post questions in there, or you can search to see if your question's already been asked. And so that group was very helpful.”

Social Groups – Participant 6: “I wouldn't have found out about the ABA (Applied Behavioral Analysis) group, the ABA place that opened up in [local location] if it wasn't for the [social media] group.”

Parental Suggestions for Improvement

In addition to identifying the barriers and facilitators to ASD diagnosis and treatment in rural and MUAs in Georgia, parents were asked what should be done going forward to improve ASD diagnosis and treatment for those living in rural and MUAs. Parental suggestions to improve issues of health disparities when navigating the healthcare system for children with ASD included: increased education for parents and healthcare providers on early signs and symptoms of ASD, enhanced public and healthcare awareness of the disorder, increased training of new ASD diagnosticians or treatment providers, better hand-off from diagnosis to treatment, and better access to care in rural and MUAs. While these are strategies that will be universally helpful and facilitative for all children and families with ASD, these ideas are particularly important for families in rural or MUAs who, by virtue of their distance from resources, must take a more informed and active role in the early development of their children and advocacy for their children's health.

One of the most significant problems reportedly faced by parents in rural and MUAs to receiving an ASD diagnosis and treatment was the lack of education and awareness about ASD in the community, schools, and healthcare. Specifically, they felt that their concerns over early red flags in their children's development were ignored by certain professionals, leading to delays in diagnosis and treatment. They also discussed how other physiological, psychological, or social disorders of childhood received more public attention and awareness compared to ASD. In order to address these concerns, parents suggested increased education, awareness, and training for professionals interacting with children on a daily basis, such as those working in the education system and pediatric-focused medical fields.

In addition to these potential solutions, parents also described how better transitions from diagnosis to treatment and access to care in their native areas would greatly ease the burden of ASD treatments in rural and MUAs. One participant suggested that after leaving an appointment with a provider who could make the ASD diagnosis, that same provider could also specify next steps and contact information to treatment providers. This parent also suggested a document list of providers in their native areas and the insurances these individuals accepted. Other suggestions for increasing access to care in these underserved areas included the following interventions: telehealth, mobile clinics, encouraging other providers to come to the area, and having healthcare students train in rural and MUAs. To implement these ideas, parents suggested the use of telehealth and mobile clinics. They also proposed that healthcare organizations offer incentives to increase the number of providers willing to work in rural and MUAs, as well as partnering with nearby schools to train students in rural areas.

Quotes from Parents Related to Ideas for Improvement

The following quotes from parents identified ways to address ASD disparities in diagnosis and treatment in rural and MUAs:

Mobile Clinics – Participant 7: “I think it will help if they brought like...mini clinics. Even, you know, something a little closer so we don't always have to drive so far out.”

Increasing Providers – Participant 8: “I think that, well, there needs to be more developmental pediatricians and...diagnosticians. So, whether it's a psychiatrist, psychologist... that can make the diagnosis.”

Training Providers – Participant 2: “...a lot of the schools like [local University] have really big [therapy programs]. In order for students to get their...ABA clinic hours, [they practice delivering ABA therapy to children with ASD]. That's why parents are able to afford it, because now these are college kids doing it for clinic hours.”

DISCUSSION

Timely diagnosis and treatment is crucial for the long-term health outcomes of children with ASD. This process can be impeded by a variety of factors, but the challenges are compounded for individuals living in rural or MUAs. Individuals in these areas face a disproportionate number of unique health disparities and barriers related to acquiring a diagnosis and accessing treatment for ASD, when compared to their urban peers [4, 17, 19].

Focus groups with parents of children with ASD living in rural and MUAs revealed a number of barriers related to both ASD diagnosis and treatment. Parents described a variety of diagnosis and treatment challenges, including limited providers in their area, excessive distance to providers, lengthy wait times for appointments, inadequate insurance coverage, lack of parental and provider education, and overall lack of awareness of ASD diagnoses and treatment in both families and clinicians. In addition, parents also mentioned the lack of follow-up care, leaving them feeling unsure of what the next steps were supposed to be after receiving their child's ASD diagnosis. Thematic analysis of parents' responses revealed perceived limited parental autonomy over their child's healthcare, frustration and disappointment with the healthcare system, and a desire for more support and education. The impact of these disparities and barriers weighs emotionally and financially on parents and families in the form of lost jobs due to time away from work to attend appointments, lost time in school for affected children and siblings, and a general sense of confusion and abandonment by the healthcare system. One parent specifically mentioned that due to the distance and necessary time-off that she had to take from her job, she ended up being fired and becoming unemployed, thus creating the cycle of poverty and perpetuating the cycle of health disparities. These barriers not only affect parents and families, but also could potentially influence the affected child's developmental and social health trajectory if not addressed appropriately.

Many rural and MUA areas are underserved, and families of children with ASD in these populations suffer disproportionately compared to their peers; however, little is known in terms of specific barriers and facilitators to diagnosis and treatment, as well as family-based interventions. This study has demonstrated the needs of underserved children and families with ASD residing in rural and MUAs in Georgia, and it addresses them specifically with a desire to know the barriers and facilitators, to engage the community, and to offer partnership in community-based pragmatic solutions. It has also drawn attention to the difficulties in recruitment and engagement of rural communities. Members of these areas are potentially vulnerable families with past negative experiences with healthcare and research, and they may be hesitant to participate in studies without rapport and understanding being built first. They also face challenges with numerous obligations of running a home and family, which

renders them unable to participate in-person in studies. However, there are ways to ensure that the voices of individuals from rural and MUAs are heard and are present in ASD research, despite any challenges that arise from their geographic locations and socioeconomic and cultural circumstances.

The use of online focus groups to engage parents living in rural allows the consideration of the pros and cons of conducting non-traditional (i.e., online) focus group research and service in these areas. Positive aspects of these nontraditional focus groups can include the chance for participants who live in distant areas to share their stories and have their voices heard when they might not be able to participate in person otherwise, enabling them to be more empowered. However, potential problems with online focus groups may involve technical difficulties when conducting them or the possibility of missing out on a more personalized, in-person interaction. Despite these challenges, research and medical care utilizing telehealth, mobile clinics, or online resources could potentially mitigate the geographic health disparities in vulnerable communities dealing with access to care difficulties. These solutions offer viable alternatives to traditional diagnostic and therapeutic services in rural and MUAs.

Future Directions

Future directions for this study, and for studying ASD disparities in MUAs, involve continuing to engage more parents, especially those living in rural and MUAs in different areas of the state, and in other states with large rural or MUA populations. Research would also benefit from engaging other stakeholders, including providers, educators, parent mentors, and policymakers, to better understand their perspective and experiences with these healthcare disparities. Finally, future research should focus on interventions to minimize these health disparities in MUAs, potentially through the use of telehealth or mobile clinics. Additional interventions, as suggested by the parents, should involve increasing ASD awareness and education to pediatric providers and individuals who work with children, such as those in the school sector. This would likely help to recognize early signs and symptoms of ASD in children and potentially aid in earlier diagnoses. Finally, statewide early interventions may consider leveraging their existing outreach, increasing visibility through social media or other shared programs, and improving existing programs to increase ASD diagnosis.

Limitations

The scope of this project was a pilot project. Thus, the sample size was limited. However, the experience and frustrations expressed by participants in this study are mirrored with other populations. Additionally, given that this population is understudied in the ASD community, the small sample size works as a pilot project for assessing the feasibility for reaching these groups, whether it be via in-person or online focus groups, as many of the families are unable to travel long distances to meet in person. Despite the small sample size, results of this study are an important first step to conducting future research in rural and MUAs, as well as

determining feasibility of tele-focus groups. This will increase the generalizability to different populations, and it could potentially lead to the development of evidence-based interventions.

CONCLUSION

Parents of children with ASD living in rural and MUAs face health disparities in the forms of barriers to accessing ASD diagnosis and treatment. A majority of barriers are centered around the lack of access to providers and challenges associated with access to care, such as limited providers in the area providing ASD specific services and issues with insurance providers not covering treatments. Potential interventions to address these barriers must be focused on patient- and family-centered care, where patients and families identify their specific needs and possible solutions to address them. According to the parents in this study, decreasing health disparities in MUAs in Georgia may be accomplished through increased education, enhanced awareness, and increasing the number of providers that are available to meet the needs of these underserved, vulnerable populations. Given that there are many states throughout the United States that have rural and MUAs similar to Georgia, this early research is key to developing interventions for many children and families affected by ASD healthcare disparities throughout the country. Such interventions could include innovative methods of delivering care, such as through the use of telehealth and mobile clinics, as well as increasing awareness of ASD for parents, providers, and educators of young children. These interventions address the factors of limited access to healthcare and educational services, inadequate infrastructure, and limited parental empowerment and stress, thus helping to break the cycle of ASD health disparities in rural and MUAs.

ABSTRACT

We enrolled 22 SLE patients (8-19 years old) over three months during clinic visits. Demographic information and medical history were self-reported and collected from medical records. Health and numeracy literacy were assessed using short test of functional health literacy (S-TOFHLA) and Newest Vital Signs (NVS), respectively. Results: Out of the 22 patients, 19 (86%) were female. The greatest percentage by race was Black (45%), and 32% of patients identified as Hispanic. The median age of the participants at the time of the study was 15 years while the median age at diagnosis was 13.5 years. All of the patients surveyed had an adequate score on the S-TOFHLA while only 36% (95% CI: 17.2%-59.3%) scored adequate on the NVS. 27% of the patients

* Corresponding Author's Email: catkwpark@gmail.com.

surveyed stated that they have been exposed to secondhand smoke, and 9% had tried cigarettes and/or other tobacco products. Conclusion: Although all of the patients surveyed scored adequate levels on the S-TOFHLA, the majority scored in the limited/inadequate range on the numeracy test. This is concerning, as numeracy skills are critical for patients to optimally take medications and follow recommendations including dietary guidelines. Based on these results, going forward, we would like to provide patient recommendations that take into account their numeracy and health literacy levels. One potential way to do this is to create patient education material for easier identification of pills and pill dosages as a first step towards increasing adherence and improving patient outcomes.

INTRODUCTION

Systemic lupus erythematosus (SLE) is a multifactorial autoimmune disease that has the potential to affect multiple organ systems. It affects people of all ages and races, but racial and ethnic minority groups are disproportionately affected with almost double in Black women when compared to White [1-3]. Childhood-onset SLE (cSLE) is commonly defined as being diagnosed at <18 years of age, and about 20% of SLE cases present in this age group. Involvement of some organ systems, such as kidneys, have been found to be more common and with higher disease severity in cSLE when compared to adult-onset SLE [4]. As of yet, the etiology of SLE is not fully understood. The presumed pathophysiology is that one has a genetic predisposition and then potential factors including environmental stresses, such as smoking, diet, drugs, and hormones trigger the development of SLE [5]. Given the variability of symptoms with the common symptoms being nonspecific, such as fatigue, weakness, and joint pains, along with symptom severity ranging from mild to severe, the diagnosis of SLE can be quite challenging. This generally results in a delay in diagnosis of about two years from the onset of symptoms [6, 7]. Additionally, achieving favorable long-term outcomes in a disease process that has a severe impact on quality of life can prove to be challenging. Successful long-term outcomes in chronic conditions depend largely on education, awareness, and developing self-management skills, which include administering medications appropriately and consistently, managing symptoms, and navigating the life style changes along with the psychosocial components of one's condition [8, 9].

A major barrier to managing chronic conditions today is non-adherence to medications and other management recommendations [10-12]. There is a high prevalence of medication non-adherence in adolescents, which puts them at higher risk for worse outcomes [13]. For SLE specifically, medication non-adherence is as high as 40% with a recent study specifically looking at cSLE showing medication non-adherence at 19.7% [14-16]. One proposed tool to improve medication adherence is to individualize patient education by focusing on health literacy and providing patient instructions based on health literacy levels. Health literacy is defined as "the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions" [17]. The 2003 National Assessment of Adult Literacy, which was a seminal study looking at adult literacy levels in the United States, was administered to more than 19,000 individuals aged 16 years and older. This study found that approximately 36% had limited health literacy levels defined as scoring at basic or below basic levels. This study along with several additional analyses of the study showed that factors, such as poverty, race/ethnicity, disability, age, and education, can all influence health

literacy levels (HLL) [18, 19]. In particular, low HLL along with low literacy in general are associated with lower income and racial/ethnic minority groups [17, 20]. This makes it crucial that HLL in disease processes that affect racial/ethnic minority groups more, such as SLE, are assessed. There is growing evidence to suggest that addressing health literacy will have significant benefits in chronic pediatric illness [20, 21].

In addition to reading, numeracy skills are an important variable when it comes to health literacy. Studies have shown that although numeracy skills can be equivalent to literacy skills, many patients actually tend to have poorer quantitative skills [18, 22]. A 2018 study done at a single pediatric center looked at health literacy, including numeracy, in pediatric kidney transplant recipients and found that 95% of the patients had adequate literacy skills but only 27% had adequate numeracy skills [23]. An adequate functional HLL is crucial to comprehend information provided by healthcare providers and develop lifelong behaviors needed for successful adherence and ultimately favorable long-term outcomes [21, 24-26].

Integrated with traditional health literacy skills is the emerging and evolving field of environmental health literacy, which is defined as “an understanding of the connection between environmental exposures and human health” and its impact on patient outcomes [27]. The 2018 data from the National Youth Tobacco Survey showed that the prevalence of tobacco product use was 27.1% in high school students, and 7.2% in middle school students; both were increased when compared to 2017 data [28]. Data on secondhand smoke exposure in children showed that the prevalence was more than 37% in 2016 [29-31], and the exposure was highest among those living in poverty as well as among non-Hispanic blacks. Several studies have shown that environmental cigarette smoke is associated with an increased risk of the development of SLE in individuals with a genetic predisposition [32-34]. Therefore, in children of a younger age with cSLE, secondhand smoke exposure also needs to be considered as a risk factor for SLE. In a disease process where environmental triggers can potentially worsen outcomes or lead to flares, it is crucial to also increase awareness of environmental health literacy.

The primary aim of this study was to determine the functional HLL, which included literacy, numeracy, and environmental, of cSLE patients in a pediatric center in Atlanta, Georgia where there are about 400 cSLE patients under the combined care of Rheumatology and Nephrology services. We determined if lower HLL were associated with increased healthcare utilization defined as number of Emergency Room (ER) visits and hospitalizations per year. Given previous results for pediatric patients with kidney transplants in the same geographic region, we hypothesize that cSLE patients in this study will have lower HLL, particularly with numeracy literacy. Since understanding of prescriptions is essential in accurately taking medications at home, lower numeracy skills may prove to be a barrier in optimal self-management leading to poorer outcomes, hence we also hypothesize that lower HLL will be associated with increased medical complications and increased healthcare utilization. A secondary aim was to estimate smoking and exposure to secondhand smoke. We hypothesize that the prevalence of secondhand smoke exposure in cSLE patients will be at the least the same or higher than the general population.

OUR STUDY

Approval for this study was obtained through the Institutional Internal Review Board. This was a cross-sectional study and a retrospective chart review over the span of 2 months (2/1/2019-3/31/2019), enrolling 22 SLE patients ranging from 8 to 19 years of age. Demographic information and medical history were collected at the time of scheduled clinic visits. Our primary outcome measures were hospitalizations and ER visits related to SLE.

Inclusion and Exclusion Criteria

Inclusion criteria for this study were cSLE patients between the ages of 8 and 21 years who speak and understand English. Parents/caretakers/guardians of cSLE patients were also able to participate if they were able to speak, read, and/or understand English. Exclusion criteria were those who could not speak, read, and/or understand English, had cognitive delay, were unable to provide informed consent, and were outside the age range of 8 to 21 years.

Survey Design

The Short Test of Functional Health Literacy (S-TOFHLA), a validated measure assessing health literacy [35], and the Newest Vital Signs (NVS), a validated measure assessing numeracy skills [36, 37], were administered during the clinic visit and the results were used to determine baseline functional HLL. Patients were also asked to fill out a secondhand smoke exposure survey, which is adapted from the CDC Youth Tobacco survey, to assess exposure [38]. Clinical information was obtained from patient's medical records from the time of SLE diagnosis to the end of the study period (3/31/2019). We used this information to determine a healthcare utilization rate defined as the total number of ER visits and hospitalizations per patient-year.

Data Analysis

Based on the results of the S-TOFHLA and NVS, individuals were classified as either having adequate HLL or inadequate HLL with adequate being a score of 23-36 on S-TOFHLA and 4-6 on NVS [35-37]. Participants were placed in the inadequate group if they scored in the inadequate/marginal range for the S-TOFHLA (0-16 and 17-22 respectively) or in the inadequate/limited range on the NVS (0-1 and 2-3 respectively). Proportions of adequate/inadequate literacy were calculated with the 95% confidence interval (CI) using the Clopper-Pearson exact method. Fisher's exact test was used for categorical data while Wilcoxon rank sum was used for testing continuous data by adequate vs inadequate groups. Poisson test was used to analyze healthcare utilization between the adequate and inadequate HLL groups. Exact confidence intervals for healthcare utilization were calculated, which is based on the binomial distribution given the small sample size.

FINDINGS

Of the 22 individuals who participated, 86% were female. The greatest percentage in race were Black (45%), while 32% identified themselves as White-Hispanic. The median age of the participants at recruitment was 15 years while the median age at diagnosis was 13.5 years (see Table 1). All of the individuals who participated scored in the adequate range for the S-TOFHLA (see Figure 1). However, for the NVS, only eight patients (36%) scored in the adequate range while the remaining 14 (64%) scored in the inadequate range (combination of high likelihood of limited numeracy skills and possibility of limited numeracy skills) (see figure 2). Of note, we attempted to assess the parents’ functional health literacy as well, but due to the scarcity of the responses, found that the data could not be analyzed meaningfully.

Table 1. Baseline characteristics of the 22 p-SLE participants

Demographics	p-SLE Patients N = 22
Gender, n (%)	
Female	19 (86%)
Male	3 (14%)
Race, n (%)	
White	9 (41%)
Black	10 (45%)
Asian	3 (14%)
Ethnicity, n (%)	
Hispanic	7 (32%)
Non-Hispanic	15 (68%)
Age at diagnosis (years), median (Q1,Q3)	13.48 (11.94, 14.56)
Duration of disease (months), median (Q1,Q3)	23 (11.04, 46.09)

Figure 1. S-TOFHLA scores.

Figure 2. NVS scores.

Table 2. Patient characteristics compared by inadequate and adequate HLL based on scores from newest vital signs (numeracy test)

Variable	Overall (n = 22)	Inadequate HLL (n = 14)	Adequate HLL (n = 8)	p-value
Age, mean (SD)	15.4 (2.3)	15.4 (2.2)	15.3 (2.7)	0.97
Age at diagnosis, mean (SD)	13.0 (2.0)	13.5 (1.8)	12.1 (2.2)	0.15
Gender, n (%)				0.53
Female	19 (86.4)	13 (92.9)	6 (75.0)	
Male	3 (13.6)	1 (7.1)	2 (25.0)	
Race, n (%)				0.69
White	9 (40.9)	6 (42.9)	3 (37.5)	
Black	10 (45.5)	7 (50.0)	3 (37.5)	
Asian	3 (13.6)	1 (7.1)	2 (25.0)	
Ethnicity, n (%)				1.00
Hispanic or Latino	7 (31.8)	4 (28.6)	3 (37.5)	
Non-Hispanic	15 (68.2)	10 (71.4)	5 (62.5)	

Table 3. Healthcare utilization rates compared by inadequate and adequate Hll based on scores from newest vital signs (numeracy test)

	Overall (n = 22)	Inadequate HLL (n = 14)	Adequate HLL (n = 8)	p-value
Duration of illness calculated (yrs), mean (SD)	2.38 (2.19)	1.89 (1.54)	3.24 (2.95)	0.27
Number of hospitalizations or ER visits, mean (SD)	5.55 (6.64)	5.71 (6.35)	5.25 (7.55)	
Healthcare utilization, ER visits/hospitalizations per yr (95% CI)		3.02 (0.63 – 8.80)	1.62 (0.14 – 6.61)	0.0011*

Since all participants scored in the adequate range under S-TOFHLA, the individuals were divided into an adequate and inadequate health literacy group based on their NVS scores. Baseline characteristics were compared by health literacy group. There were no statistically significant differences in age, gender, race, ethnicity, and duration of disease between the groups. The mean (SD) age in years was 15.4 (2.2) for the inadequate group and 15.3 (2.7) for the adequate group. The mean (SD) age in years at diagnosis for the adequate HLL group was 12.1 (2.2) and 13.5 (1.8) for the inadequate HLL group although this difference was not statistically significant (Table 2). The inadequate HLL group had an average (SD) of 5.71 (6.35) number of hospitalizations/ER visits for the individuals' disease course compared to 5.25 (7.55) per disease course for the adequate HLL group. However, if we take into account the actual duration of illness/follow-up, a significant difference was present between the groups. The eight adequate HLL individuals had a healthcare utilization rate of 1.62 (95% CI 0.14 – 6.61) per patient-year, while the 14 inadequate HLL individuals had a healthcare utilization rate of 3.0 (95% CI 0.63 – 8.80) per patient-year. Therefore, using a Poisson test, a significant difference was detected in healthcare utilization by group (Table 3).

In regard to the secondhand smoke survey, 27% of the individuals surveyed stated that they have been exposed, and 9% reported trying cigarette and/or other tobacco products. Those who reported trying tobacco products stated that they were not exposed to secondhand smoke.

DISCUSSION

To our knowledge, there are a lack of studies looking at functional health literacy in cSLE patients and its effect on clinical outcomes. A few small studies on adult SLE patients show that a low HLL was present in about 20-50% of the population and was associated with worse chronic organ damage and patient reported outcomes [39, 40]. Generally, assessing pediatric health literacy can be more complex given the developing literacy skills of pediatric patients along with the need for adequate parent or caregiver's literacy levels. Therefore, health literacy in both the pediatric patients and their caregivers need to be carefully assessed and addressed [41]. This is imperative for a disease process that is known to be more prevalent in lower socioeconomic groups since low health literacy is an important underlying factor in further widening the gap in healthcare disparities [42].

The results of this study show that the demographics of our small sample size are similar to previous cSLE studies with the majority of the sample being female and from a racial or ethnic minority group. Although 100% of the individuals surveyed scored at adequate levels on the S-TOFHLA, the majority scored in the limited/inadequate range for their numeracy skills based on the NVS. In an age group where medication adherence is already problematic, these results are concerning. Since SLE is known to affect multiple organ systems, the majority of patients are responsible for managing multiple prescriptions, and numeracy skills are vital in accurately interpreting and optimally adhering to these prescriptions. If an individual also has renal involvement, it is critical to be able to read food labels and determine how much sodium, potassium, and phosphorous are in the foods, which requires adequate numeracy skills.

A recent study in 2018 looked at health literacy disparity and its effect on adolescents and young adults with chronic or end-stage kidney disease [43]. Results from this study did not show major differences between low and adequate health literacy groups on healthcare utilization defined as preventable hospitalizations, total hospitalizations, length of hospital stay, and ER visits [43]. For the cSLE patients surveyed in our study though the results did indicate that healthcare utilization, defined as ER visits and hospitalizations pertaining to SLE, differed between low and adequate health literacy groups. According to patient reports, SLE has a tremendous impact on the quality of life of patients, caretakers, family members, employment, financial status, and work productivity [44]. Therefore, the ultimate goal in SLE management is to get patients on an effective maintenance medication regimen to prevent flares/relapse and eventually improve quality of life for both the child and the family. Our results indicate that the group with inadequate HLL had increased utilization of healthcare services, which suggests an increased risk for worse outcomes.

Figure 3. Breaking the cycle of health disparities related to health literacy including numeracy skills and environmental health literacy.

The estimate of health literacy was the primary focus of this study. Although the utilization rates were not compared for all possible confounders due to small sample size, these results still indicate that the need for counseling and instruction based on one's health literacy level may be an optimal point of intervention to break the cycle of health disparities for children with SLE (see Figure 3). In particular, health literacy interventions targeting high-risk groups, such as cSLE patients, may improve outcomes and ultimately break the cycle of health disparities. Given SLE affects minority groups more often and a lower socioeconomic status is associated with more severe disease, the cycle of health disparities is perpetuated by resources that may not be appropriate for those with limited education and/or lower HLL. Several resources are available to these patients, either in the form of online material, written pamphlets, or written instructions from the providers, but resources are of limited value if the individual is not able to read, understand, remember, and adequately act

on the instructions at home. A recent randomized controlled trial showed a statistically significant and clinically meaningful effect on medication decision making in patients with lupus nephritis when using a computerized decision aid that is individualized and culturally tailored compared to an American College of Rheumatology lupus pamphlet [45]. One possible indicator of poor health literacy is identification of pills by the color and size and not by their names. One way to combat misidentification of medications due to the inability to identify them by name is to provide patients with pictures of commonly used SLE medications and demonstrate which pills and how many of them to take [46-48]. Studies done in pediatric diabetic patients and parents have shown that hands-on demonstration of how to dose medications have been helpful particularly for individuals with low HLL [49]. Another key intervention is the teach-back/show-back method, which has been confirmed in several studies to be highly effective in improving communication and confirming understanding [50-52]. Ultimately, our recommendation would be to individualize the education process based on each individual's education status as well as health literacy level.

This study also revealed that about a quarter of the cSLE patients were exposed to secondhand smoke, which is less than the prevalence for the general population. This is interesting given that the cSLE patients tend to have the demographics of individuals with higher risk for secondhand smoke exposure. What the smoking survey was not able to adequately ascertain though was the difficulty that participants had in not fully understanding the concept of secondhand smoke exposure. This observation suggests that, although this was not formally tested, environmental health literacy may be inadequate in this patient population as well as not discussed adequately by the providers. Further evaluation of this along with increased awareness for our patients are needed.

Limitations

One of the major limitations to this study is the small sample size. The majority of the individuals with cSLE were recruited in the general nephrology or rheumatology clinic setting as opposed to in the end-stage renal disease clinics, such as chronic kidney disease, dialysis, and transplant clinics. This could potentially represent a selection bias since the individuals with more significant disease and potentially lower HLL and limited transportation resources may not come to clinic as often. There is also a chance that patients with perceived lower HLL declined to participate due to fear of taking a literacy test although only two patients declined to participate. Another limitation is that this data analysis did not take into account any potential confounders, such as income, education level, minority status, which could affect our results. Furthermore, the ER visits and hospitalizations counted in this study were only those that occurred at our single center so if patients went to other ER's or were hospitalized at other hospitals, they were not counted, which could skew results. Of note, the hospital assessed in this study is the main hospital that provides pediatric rheumatology and nephrology care to the majority of Georgia. Therefore, most of the patients with cSLE in Georgia are likely to attend the clinic at this hospital and are likely to visit this specific hospital's ER, be admitted to this particular hospital, or at least contact the clinic when there is a concern. At this age, some of the medical management is still done by parents, which was not asked in the surveys. If the medical care is strictly managed by the parents or other

caregivers, then it is crucial to determine their HLL as well. One of the exclusion criteria in this study was not being able to speak, read, and/or write English; however, the subjects were not asked what the primary language was spoken at home, which could potentially affect literacy levels.

Future Directions

Results of this preliminary study were suggestive that HLL can potentially affect one's outcomes. Therefore, the next steps would be to recruit more caregivers if they are doing the majority of the medical management as well as do further data analyses to account for the aforementioned limitations. The take-home message is to focus the efforts on individualizing the education process, and in turn, improve communication between the providers and the patients with lower HLL. One plan for the future is two-tiered. The goal is to increase awareness amongst the providers about the potential for patients to have limited HLL as well as create optimal educational materials for our cSLE patients for easier identification of medications so that they can successfully demonstrate the teach-back method. These interventions can ultimately improve home management and aide patients in decreasing medical complications and potentially achieving better quality of life and thus break the cycle of health disparities for children with SLE.

Chapter 341

DID MEDICAID EXPANSION DECREASE DISPARITIES FOR RECEIPT OF PREVENTIVE MEDICAL CARE AMONG VULNERABLE CHILDREN?

ABSTRACT

In this chapter we investigate differences in receipt of pediatric preventive medical visits (PMV) among racial/ethnic groups between the states that did and did not expand Medicaid as a part of the 2010 Affordable Care Act. Differences were investigated using hierarchical linear modeling. Tested models included whether respondents were first generation immigrant families, if English was spoken in the home, whether the child had special health care needs, if there was an insurance gap, and race/ethnicity of the child as level-1 variables and residence state as a level-2 variable to predict odds ratios of PMV, with cross-level interactions between race/ethnicity and Medicaid expansion. All groups of children living in states with Medicaid expansion had increased log-odds of receiving a PMV. When the interactions between race/ethnicity and Medicaid expansion were considered, the odds of PMV among Whites, Hispanics, Black, and other race/ethnicity children was greater in Medicaid expansion states; however, the strongest effect was for White children. If the interaction term was not considered, children of Hispanic and Other ethnicity had significantly lower odds of receiving PMV in both expansion and non-expansion states. Children who did not speak English in the home, were first generation immigrant families, and/or experienced a gap in insurance had reduced odds ratios for receiving PMV compared to other children.

INTRODUCTION

The Affordable Care Act of 2010 (ACA) was introduced to improve health care coverage for United States citizens. The ACA included a goal to expand Medicaid to cover all families below 138% of the poverty level [1], but not all states opted to expand Medicaid coverage. Medicaid is a public health insurance program, funded by a combination of federal and state monies. Both federal and state funds are managed by the states, resulting in many different approaches to administering Medicaid [1]. Prior to 2014 the median income to qualify for Medicaid was \$15,000 for a family of four, with wide variation from state to state. Children's health benefits were mandated by the federal government through the Children's Health Insurance Program (CHIP) program for children whose family income fell below 100% federal poverty level, \$23,842 for a family of four [1]. After 2014 the median income for a family of four qualifying for Medicaid rose to \$33,465. All states lost federal funding for uncompensated healthcare as part of the ACA, but these losses were expected to be balanced with a greater proportion of healthcare costs paid through Medicaid [1, 2]. As funds for uncompensated care were reduced--in all states--the number of people covered by Medicaid did not increase, but decreased in non-expanded states, due to changes in waiver legislation. The states that did not expand lost a large portion of their federal funding for healthcare [2]. The monies that had been flowing to uncompensated health care were diverted to Medicaid, so if a state did not expand Medicaid, it generally lost funding.

While the ACA expansion was primarily aimed at adults, the fact that children follow their caretakers into insurance coverage suggests that children should reap benefits as well [3]. It is reasonable to expect that the Medicaid expansion increased children's access to health care. One important outcome of Medicaid expansion is whether children have increased access to a preventive medical visit (PMV), an indicator of children's access to preventive health care [4]. Preventive health care is important for connecting children to health care providers who promote health, teach caretakers and children to make better health decisions, and help prevent and/or detect disease early [5]. During a preventive health visit children and caretakers receive guidance in promoting physical, emotional, and intellectual development. This help includes guidance to choose appropriate nutrition, exercise, and safety habits such as car seat and helmet usage [6]; talking and reading to promote intellectual development [7]; education and interventions to prevent or reduce adverse childhood events [8], and screening for developmental delays and behavior [5]. Further, during these visits children receive vaccinations to prevent disease and reduce health care costs over time [9].

Figure 1. Breaking the cycle of children's environmental health disparities.

Thus, children who receive preventive health care are also less likely to experience preventable illness and more likely to receive timely intervention for health conditions that are not preventable [5]. Timely intervention often reduces morbidity and mortality, allowing children longer life spans [5]. Thus, PMVs are an important outcome to consider in relation to the ACA Medicaid expansion. Reducing disparities in PMV can break the cycle of environmental health disparities by reducing the disproportionately negative effects of both social and physical determinants of health to which vulnerable children are exposed (see Figure 1).

Medicaid Expansion and Health Disparities

Health disparities among children in the USA are well documented [10]. Children of minority race or ethnicity had less desirable health outcomes on many measures including less access to care, lower quality care, and greater morbidity and mortality from disease [11, 12]. These inequities existed in preventive health care [10] even as preventive care was being promoted to reduce health disparities and reduce health care cost in the US [13].

The ACA is seen as successful in certain respects, as large disparities in healthcare insurance coverage found prior to the ACA were reduced after Medicaid expansion among all racial and ethnic groups, although not equally among all groups [14]. Research concerning children's healthcare outcomes in states with Medicaid expansion includes findings of decreased infant mortality [15], reduced disparities in trauma care in adolescents [16], increased school readiness [17], and increased access to mental health care for youth [18]. Studies indicate that Medicaid expansion is associated with increased adult preventive care [19] and that there is an increased likelihood of a well child visit among children of low income parents in states with increased eligibility for Medicaid, i.e., as the threshold for Medicaid eligibility is reduced by increasing percent of federal poverty level for eligibility, the probability of a well child visit increases [20]. In the study by Venkataramani et al [20] the data source was 2001-2009 Medical Expenditure Panel Surveys, thus it does not address differences related to ACA Medicaid expansion.

Factors Affecting Pediatric Health Care Utilization

There are many factors affecting health care utilization. For example, Anderson's Model of Health Care Consumption [21] suggests that health care consumption is predicted by need, access, and predisposing variables. Predisposing variables include demographics such as age, race, language, income, caretakers' education, family structure, and beliefs; need variables include children with special health care needs (CSHCN) that are more than the health care needs of typically developing children; access variables include health insurance, prior use of the healthcare system, and geographic location [22]. Researchers suggest that language can influence a caretaker's assessment of care quality and trust, informing their decision to take a child to a well care provider [23]. Also immigrants use less preventive health services than natives [24]. Furthermore, community poverty is associated with the emergence of health

service “deserts”, medically underserved areas or populations, where there are limited healthcare services [25].

Research Questions

In the current climate of debate concerning the efficacy of the ACA and Medicaid expansion it is important to determine what, if any, impact Medicaid expansion had on the health care outcomes of US citizens. Our study’s goal is to compare the receipt of preventive medical visits among children who lived in states that did, and did not, expand Medicaid.

Table 1. Number of children sampled in each state

State	N	State	N	State	N	State	N

Total sample size of individuals = 50,212.
Total number of clusters = 51.

This study focused on the question: Are children of all races and ethnicities living in Medicaid expansion states more likely to receive preventive health care than in non-expansion states? This study aimed to determine if (a) there are differences among states in the likelihood of receiving a preventive medical visit, (b) if these differences can be attributed to Medicaid expansion, and (c) if disparities among groups of racial and ethnic children’s receipt of PMV persist after Medicaid expansion.

OUR STUDY

The data source was the 2016 National Survey of Children’s Health (NSCH), a cross-sectional survey conducted by the US Census Bureau [4]. This survey is used to assess the physical and mental well-being of US children ages 0-17 years. A caregiver responded to inquiries focused on the health and health care of one child living in the household in 50,212 randomly selected households [4]. Table 1 contains the distribution of the sampled children among the states. Most questions required either a yes/no or a categorical response. The data source for statewide policies was the National Council of State Legislators’ database of state legislation [26]. The measurement was whether the state did or did not participate in Medicaid expansion before 2016.

Figure 2. Anderson's model of health care consumption. Anderson (Andersen RM. Revisiting the behavioral model and access to medical care: Does it matter? *J Health Soc Behav* 1995;36(1):1–10) suggested three types of variables predict health care consumption, predisposing, need based, and access. Our model is focused on the interaction between predisposing variables of race/ethnicity and access increased by living in a Medicaid expanded state.

Outcome and Predictors

The outcome variable PMV was the caregiver's yes or no response to the question "Did the child receive one or more PMV in the last 12 months". 433 children (0.8%) were missing the outcome variable, PMV, and their data was deleted from the analysis during model building.

Andersen's model of health care utilization [21] was used to select predictor variables, illustrated in figure 2. The predisposing variables included were speaking English in the home, first generation immigrant families, and race/ethnicity. These choices were based on the research question connecting persistent disparities to Medicaid expansion. The need variable was CSHCN, this is the 2016 NSCH indicator for children who need more healthcare than typical children. Caretakers responded to a series of questions that screened the child as CSHCN or not according to the criteria estimated by the Maternal Child Health Bureau [4]. Access variables were insurance gap and state of residence, insurance gap indicating if the child was insured the full 12 months prior to the survey, and state of residence indicating if the child was living in a state that did or did not expand Medicaid.

Immigration and language have been identified in other studies as predictors of PMV [11, 23] suggesting that first generation (family) and English speaking in the home might be significant predictors for this study. The focus of this research was on disparities among race/ethnic groups. Prior studies have shown that poverty level, family structure and parental education are correlated to race/ethnicity and these are important demographic factors associated with the impact of the ACA [27]. We chose race/ethnicity as predictors over the other characteristics as recent research on adults indicates that the ACA expansion has benefited White populations to a greater degree than other minority groups [14]. We included insurance gap in the prior year because Medicaid expansion is aimed at increasing health insurance coverage within the states' populations. Medicaid expansion, the only level-2 (state level) predictor, is a state level policy that may help determine the child's access to health insurance.

The outcome and predictor variables were coded as follows: Children who received PMV were coded PMV = 1, children who did not receive PMV were coded PMV = 0; children who spoke English in the home were coded English = 0, children who did not were coded English = 1; children who were not first generation were coded FirstGen = 0, children who were first

generation were coded FirstGen =1. The race/ethnicity indicator in the 2016 NSCH has four categories: Black, Hispanic, Other, and White. Each child is assigned to only one of these categories in the survey. Children who were categorized as Hispanic were coded Hispanic = 1, all other children were coded Hispanic =0; children who were categorized as Black were coded Black = 1, all other children were coded Black = 0; children who were categorized as Other were coded Other =1, all other children were coded Other =0; children who were categorized as White were coded Hispanic =0, Black =0, and Other = 0, making White the reference group for the race/ethnicity variable. Children identified as CSHCN in the survey were coded CSHCN = 1, other children were coded CSHCN =0. Children who experienced an insurance gap in the prior 12 months were coded Gap = 1, other children were coded gap =0. The states that expanded Medicaid were coded Exp = 1, the other states were coded Exp =0.

A cross-level interaction was included in the final model to study the interaction between race and Medicaid expansion among the states. The cross-level interaction was added to the level-2 model for Hispanic, Black, and Other.

Analysis

A Hierarchical Generalized Linear Regression (HGLM) model was built using HLM 7.03 [28]. HLM software uses a Bernoulli link function and penalized quasi-likelihood estimation method to produce log-odds of PMV. The unconditional model, predicting the log-odds of an average child in the study receiving PMV with no predictor other than state, separated the model variance into individual variance within the states and state level variance between the states. This model produced an intraclass correlation coefficient of .04, suggesting that 4% of variance was related to state differences, and that a hierarchical modeling approach was appropriate for this study.

Variables in the model were uncentered and all slopes fixed because 51 clusters were too few to allow for random slopes. The model was constructed without interaction terms, and then with cross-level interaction terms for the variables first generation, non-English in the home, Black, Hispanic and other. The interaction terms for first generation and non-English in the home were not significant. The interaction terms for Black, Hispanic, and Other were significant. The final model was built including only interaction terms for the set of race/ethnicity variables, Black, Hispanic, and Other. The final fully conditional model was:

$$\ln \left(\frac{\Pr(PMV_{ij}=1)}{1-\Pr(PMV_{ij}=1)} \right) = \beta_{0j} + \beta_{1j}(English) + \beta_{2j}(FirstGen) + \beta_{3j}(Gap) + \beta_{4j}Hispanic_{ij} + \beta_{5j}Black_{ij} + \beta_{6j}Other_{ij} + \beta_{7j}CSHCN_{ij}$$

$$\beta_{0j} = \gamma_{00} + \gamma_{01}Exp_j + u_{0j}; u_{0j} \sim N(0, \tau_{00})$$

$$\beta_{1j} = \gamma_{10}$$

$$\beta_{2j} = \gamma_{20}$$

$$\beta_{3j} = \gamma_{30}$$

$$\beta_{4j} = \gamma_{40} + \gamma_{41}(Exp_j)$$

$$\beta_{5j} = \gamma_{50} + \gamma_{51}(Exp_j)$$

$$\beta_{6j} = \gamma_{60} + \gamma_{61}(Exp_j)$$

$$\beta_{7j} = \gamma_{70};$$

In this model γ_{00} was the expected log-odds of having a PMV for a referent child described as one who: (a) speaks English in the home, (b) is not first generation, (c) had no insurance gap, (d) is White race, (e) does not have special health care needs and (f) lives in a state without Medicaid expansion. γ_{01} represents the expected log-odds of having a PMV in a state that has Medicaid expansion compared to the log-odds in a state that does not, holding all other variables constant. The $\gamma_{10, 20, 30, 40, 50, 60, \text{ and } 70}$ estimates represent changes in log-odds--controlling for other variables in the model—among children different from the reference group in each predictor category, that is a child who (a) does not speak English in the home, and/or (b) is first generation, and/or (c) had an insurance gap, and/or (d) is of Black, Hispanic, and/or Other race/ethnicity, and/or (e) has special health care needs.

Assumption Checking

Assumptions underpinning the use of a 2-level binomial model were checked to determine if this set of predictors and outcome were appropriate for use in HGLM. Pearson correlations among the level-1 predictors and level-1 residuals were calculated and the level-1 predictors were determined to be independent of the level-1 residuals. Pearson correlations among the level-1 predictors were determined and the only highly correlated pair was not speaking English in the home and Hispanic. Not speaking English in the home and Hispanic had a .46 correlation, but both predictors were included because the literature search suggested parental language as an important predictor of PMV [11], and race/ethnicity form the research questions. The level-2 residuals were reasonably normal. There was no correlation between level-2 residuals and level-2 predictors, suggesting independence. There was no correlation between level-1 residuals and level-2 residuals, suggesting they were also independent. The omitted level-1 predictors of poverty level, sex, age, and family structure were not correlated to the level-2 residual.

Table 2. Characteristics of population estimated by the sample

Variable	Sample N	Level	Estimated Population N	Proportion	SE
Preventive Medical Visit	42344	Outcome	59647331	0.81	0.001
No Preventive Medical Visit	7435	Outcome	12858597	0.18	0.001

FINDINGS

Population estimates, shown in table 2, were found for the proportions of children with the outcome and predictor variables included in the model. The questions concerning first generation and language spoken in the home had a higher rate of missing responses than other predictors, eight percent and four percent, respectively. All other variables had less than one percent missing responses. 81% of all children were estimated to have received a preventive medical visit in the previous 12 months. An estimated 86% of children spoke English in the home, 10% did not speak English in the home and 4% of respondents did not answer this question. An estimated 89% of respondents said the child being surveyed was not first-generation, 3% of caregivers responded that the child in the survey was first-generation, and 8% of the caregivers did not answer this question. An estimated 91% of children did not experience an insurance gap in the 12 months preceding the survey, 8% did experience an insurance gap. 19% of children were estimated to have a special health care need, 81% did not have a special health care need. Twenty-six of the states included in the 2016 NSCH states expanded Medicaid prior to data collection in 2016.

EXP, γ_{51}	-0.26	0.77	(0.64,0.94)

Only fixed effects are reported in this table because there are no random slopes in the final model.

Results of Model Building

Results of HGLM analysis suggested that children living in Medicaid Expansion states and children with special health care needs were more likely to receive PMV than children who did not live in expanded states and/or who did not have special health care needs, as

shown in table 3. The odds ratio for PMV among children in expanded states was 1.53, 95% CI = [1.26, 1.86] times those of children in non-Medicaid expansion states. The odds ratio for PMV among children with special health care needs was 1.72, 95% CI = [1.59, 1.86] times those of children who did not have special health care needs.

Several predictors in the model reduced children's odds ratios for PMV. These were first generation, insurance gap, and not speaking English in the home. Odds of PMV among first generation children were 0.64, 95% CI = [0.45, 0.89] times those who were not first generation, odds of PMV among children who experienced an insurance gap in the prior 12 months were 0.63, 95% CI [0.53, 0.75] times those of children who did not experience an insurance gap, and odds of PMV among children who did not speak English in the home were 0.62, 95% CI [0.25, 0.75] times those of children who spoke English in the home.

The race/ethnicity variables were analyzed with cross-level interaction terms added to the final model. The coefficient for cross-level interaction for other was -.26, p-value = .009; the cross-level interaction coefficient for Hispanic was -0.19, p-value = .06, and the cross level interaction coefficient for Black was -0.30, p-value = .05.

Figure 3 is a chart showing the odds ratios for all four race/ethnicity categories in Medicaid expansion states and non-Medicaid expansion states including the interaction between Medicaid expansion and race/ethnicity. The negative interaction coefficients in table 3 suggested that non-White children in Medicaid expansion states had lower odds of PMV than children who were White, but children in all four race/ethnicity categories had increased odds of PMV in Medicaid expansion states versus non-Medicaid expansion states.

Figure 3. Odds Ratios for PMV produced by the model including interactions between Medicaid expansion and race/ethnicity. The graph illustrates the negative interaction between Hispanic, Black, and Other race/ethnicities in Medicaid expansion states—the odds ratio for White children are noticeably higher than the other three. The coefficients for the Hispanic and Black race/ethnicity are not statistically significant, the coefficient for Other is statistically significant. The slopes for White and Black are greater than Other and Hispanic, suggesting that Medicaid expansion had a greater impact on White and Black children's receipt of PMV.

Holding all other variables constant, the equation for determining the effects of Medicaid expansion among the race/ethnic groups is:

$$\ln \left(\frac{\Pr(PMV_{ij}=1)}{1-\Pr(PMV_{ij}=1)} \right) = \gamma_{00} + \gamma_{30}(\text{Hispanic}) + \gamma_{40}(\text{Black}) + \gamma_{50}(\text{Other}) + \gamma_{01}(\text{Exp}) + \gamma_{31}(\text{Hispanic}) * (\text{Exp}) + \gamma_{41}(\text{Black}) * (\text{Exp}) + \gamma_{51}(\text{Other}) * (\text{Exp})$$

The race/ethnicities were dummy coded, with White as a reference group. Substituting ones for the desired race and zeros for the other races determined the log-odds for PMV among the group of interest. The log-odds for White children is simply $\gamma_{00} + \gamma_{01}(\text{Exp})$. In this equation the odds ratio of White children receiving PMV in Medicaid expansion states was 7.61, in non-expansion states it was 5.25. The odds ratio of Hispanic children receiving PMV in Medicaid expansion states was 6.17, in non-expansion states it was 4.48. The odds ratio of Black children receiving PMV in expansion states was 5.47, in non-expansion states it was 4.50. The odds ratio of Other children receiving PMV in expansion states was 5.89, in non-expansion states it was 4.85.

Figure 4. Odds ratios produced from the model that did not include a cross-level interaction between race/ethnicity and Medicaid expansion. In this chart the interaction term is not used in the model. Black and Hispanic have similar odds ratios, Hispanic is obscured by Black. Hispanic is statistically significantly different from White, but Black and other are not.

Figure 4 is a chart comparing odds ratios among the racial/ethnic groups ignoring the interactions between Medicaid and PMV. In this model the odds ratio for PMV among children in expansion states is 1.42 times the odds ratio for children in non-expansion states 95% CI= [1.17, 1.72]. In this chart the slopes between Medicaid expansion and non-expansion states are equal because the interaction term is missing. All four race/ethnic categories of children in Medicaid Expansion states had greater odds ratios for PMV than children in the same categories in non-expansion states.

DISCUSSION

These findings suggest that children in Medicaid expansion states had a higher probability of receiving a PMV than children in non-Medicaid expansion states. The results from the models with and without interaction terms both suggest that Medicaid expansion potentially had a positive effect on children's receipt of PMV, regardless of race or ethnicity. The reduced log-odds for children who are Black or Hispanic echo findings of disparities in insurance coverage among racial/ethnic groups after passage of the ACA [14]. Disparities among the races and ethnicities remain in both expansion and non-expansion states and appear to be amplified in expansion states. This finding, which seemed counter-intuitive, appears to fit a pattern of exaggerated disparities that occur when health systems undergo reform [29]. The 2013 annual report from the Agency for Healthcare Research and Quality suggested that states with higher health care quality scores also tended to have higher disparities among racial and ethnic groups, while states with lower health care quality scores tended to show lower disparities in care among racial and ethnic groups [30, 31].

Historic and systemic inequities (for example, the Home Owners Loan Corporation's "redlining", or color-coding, of neighborhoods by race and associating lending risk with the color coding) removed vulnerable populations to less desirable and less served areas, making it harder to physically get to healthcare providers. Systemic inequity reduced vulnerable populations' ability to receive and understand information (for example, by 2014 sixteen states had passed laws regulating navigators—assistants who help vulnerable populations in understanding and purchasing insurance in the ACA marketplace [30, 32]) and created disparities in the ways that vulnerable populations were able to take advantage of healthcare reform. Although all groups in the expanded states are receiving PMV at higher rates than their corresponding groups in non-expanded states, our results suggest that White children seem better positioned to take advantage of the changes in healthcare.

PMVs are considered critical components of children's health and wellbeing, particularly in relationship to ongoing surveillance of physical and developmental health concerns. That children in Medicaid expansion states have an increased probability of receiving PMV resonates with the well-known impact that having affordable insurance can have on accessing healthcare. That said, while the expansion of ACA creates an opportunity for affordable healthcare, it does not completely relieve populations from the ongoing effects of other social determinants of healthcare access.

It is notable that disparities continue to exist in ACA expansion states, and potentially speaks to the greater realities of accessing healthcare for many minority families, particularly those experiencing poverty [10]. The ACA makes health insurance more affordable for more families, but it does not alleviate all barriers to healthcare. Impoverished children's caregivers are more likely to have caretakers working multiple jobs in order to make ends meet and may have less flexible schedules available to coordinate healthcare visits. Furthermore, transportation concerns may be more frequent in minority populations who may have less reliable sources of transportation, forcing parents to cancel appointments because of transportation issues. Lack of transportation could be compounded by the fact that minority populations are also more likely to live in a "medical desert," an area where few or no health care providers are available [25]. While the ACA has had beneficial effects, it is one policy aimed at eliminating disparities painted on a canvas of 150 years of policy that created

disparities [30]. Even as Medicaid expansion accentuated disparities in children's receipt of PMV it simultaneously reduced barriers to PMV and is helping break the cycle of disadvantaged populations who have carried a disproportionate burden of morbidity and mortality in the US.

Figure 5. States that expanded Medicaid prior to data collection for the 2016 NSCH. This map illustrates the geographic clustering of states that did and did not expand Medicaid before 2016 NSCH data collection.

Ultimately, the data presented here indicate that ACA expansion is associated with some degree of improvement in healthcare access for all children; however, being in an ACA expansion state does not necessarily ensure ready access for all. The issues of poverty, transportation, medical deserts, and other social maladies more likely to be faced by minority populations continue to exacerbate unequal healthcare access, even in ACA expanded states. To be sure, a key to open the door to a healthcare office is a good thing, but if there is no road to the door, or a reliable means of transportation, then some citizens will still not have access to affordable healthcare.

Limitations

The current analysis is largely framed as a consideration of healthcare access in relation to ACA expansion with an emphasis of ongoing racial and ethnic discrepancies in PMV receipt. The differences between receipt of PMV among the race/ethnic categories in this study might be attributable to other predictors not included in our models, including the demographics of the states. Perhaps differences in the racial/ethnic makeup, rurality, poverty, or other political policies of the states that expanded and did not expand may account for the differences we found. Another study might be strengthened by including state level variables that measure these differences. Prior research [27] suggests that there is spatial autocorrelation among the states that expanded and did not expand Medicaid. Figure 5 is a map of the states that expanded Medicaid in the time period before data collection for the 2016 NSCH illustrating their geographic clustering. The states that chose to expand Medicaid may share similar demographic and political characteristics, and the states that did not chose

to expand may share different demographic and political characteristics. Another limitation is that the study does not include individual level predictors that could account for health care consumption. The inclusion of such predictors might improve the model, but with a cost of increased multicollinearity and potential model misspecification.

Future Work

The next step for this inquiry is to apply a similar analysis to the 2017 NSCH [4]. Since Medicaid has continued to expand; the newer survey would include more states that have expanded and may paint a different picture of the impact of Medicaid expansion on pediatric PMV. It may also be informative to compare older versions of the NSCH from 2007 and 2012 to consider how these relationships have changed over time, though changes in the NSCH design will prevent firm comparison. Further investigation into differences in state policy regarding how providers interact with Medicaid would also provide beneficial information. Additionally, there may be subtle factors influencing the provider's willingness to accept Medicaid patients and that may have an impact on pediatric PMV.

ABSTRACT

Poor neighborhood quality (NQ) is associated with social withdrawal and low self-esteem, as well as increased symptoms of anxiety and depression. The majority of reports assessing the association between NQ and child mental health use Census data, which rely on objective components of neighborhood composition and cannot capture a resident's perception of the neighborhood environment. This study used longitudinal measures of maternal self-reported NQ to assess the impact of NQ patterns in middle childhood on children's mental health, in a low-income, minority population that largely resides in gentrifying Northern Manhattan neighborhoods. When children were 5, 7, 9 and 11 years old, self-reported neighborhood information was collected, and neighborhood stress was used as the metric for NQ. Symptoms of anxiety and depression were assessed using the Revised Children's Manifest Anxiety Scale (RCMAS) and the Children's Depression Rating Scale (CDRS) in early adolescence at age 9-12 years. Children of mothers who rated their total NQ as "stressed" in middle childhood had significantly more symptoms of depression than children of mothers who reported their NQ as "non-stressed" ($p = 0.046$). Additionally, there was an observable difference in the number of individuals who reported clinically significant counts of depressive symptoms between mothers who reported stressed versus non-stressed NQ (10% vs. 6%, $p = 0.20$). There was, however, no association between NQ and total anxiety. Unlike Census data, self-report NQ assessments can be used as a tool to gauge residents' subjective experience in the neighborhood and to highlight how gentrification may benefit some child residents disproportionately.

INTRODUCTION

Over the past 20 years, the relationship between neighborhood composition and children's health has become increasingly well-established. Depending on the quality and frequency of a child's interactions with his or her neighborhood, environmental context can shape youth developmental outcomes. Variations in neighborhood quality (NQ) have been associated with childhood and adolescent cognitive differences in educational achievement, verbal ability, and working memory [1-8]. With regard to socioemotional outcomes, stronger neighborhood economic resources, increased resident involvement, and increased resident employment are associated with better parent report of children's mental health and fewer parent-reported internalizing behaviors, such as social withdrawal and low self-esteem [9-11]. Conversely, both living in a low socioeconomic status (SES) neighborhood and exposure to violence have been associated with increased levels of child and adolescent symptoms of depression and anxiety, as measured through parent and self-report [11-14].

In the field of children's health, this body of research emphasizes that investigations into environmental influences on children's mental development cannot be fully complete without considering the neighborhoods in which they live and grow. Despite robust NQ examinations, there remains a gap between analyses utilizing Census data and those that use residents' self-

reported NQ assessments. Most studies observing a significant relationship between neighborhood makeup and children's health use area-level measures (e.g., Census), which rely on sociodemographic measurements of income, racial and ethnic composition, residential instability, and unemployment [15]. While Census collections can be thorough, they are entirely objective, and some researchers argue they have the potential to weaken the observed linkage between place of residence and health [16]. The systematically collected material does not measure neighborhood context and how individuals subjectively perceive their environment, in turn silencing elements of neighborhood satisfaction, structural and institutional problems in the neighborhood, relations with neighbors, and feelings of safety, all of which have been associated with resident well-being [17].

Furthermore, the use of Census data in children's environmental health studies is insufficient when trying to capture quickly changing neighborhood characteristics and how these might impact NQ perception and children's health, as a Census is only collected once every 10 years. This limitation, in addition to the Census' inability to capture an individual's perception of the neighborhood, is particularly relevant when monitoring how low-income, minority children are affected by the rapid gentrification of urban American cities. Importantly, this growing and often neglected demographic is more likely to live in disadvantaged, urban neighborhoods, due to the historical social and economic isolation of poor communities of color [1, 18–20]. Many of such neighborhoods, including the neighborhood of participants in the present study, are quickly being gentrified [20, 21]; however, how this phenomenon is impacting the health of existing child residents is largely unexplored.

Gentrification refers to the transformation of low-income, divested communities through the influx of investment and new residents with high SES [22, 23]. Resulting increases in taxes and property value often raise the community's cost of living, creating a significant financial burden for long-time residents [24]. While Census data can measure long-term socioeconomic differences in NQ following reinvestment, it cannot measure how some residents may benefit from gentrification disproportionately and how this may influence perception of the neighborhood. This is an important distinction, as research suggests parent perception of NQ can act as a mediator between neighborhood environment and children's health [3, 25].

Thus, a gap in children's environmental health literature is evidenced by the shortage of analyses exploring the impact of longitudinal self-perceived NQ on children's mental health. This gap is especially relevant as researchers begin to analyze the health consequences of low-income, minority children residing in gentrifying communities. The goal of this study was to strengthen the relationship between longitudinal self-perceived NQ and differences in children's mental health (see Figure 1). We believe that after this relationship is established, future studies should connect individual NQ differences with indicators of neighborhood gentrification. Combined, this research can reveal the disproportionate benefits to children of reinvestment in a community and, ultimately, identify levers that can help all children living in gentrifying neighborhoods benefit from reinvestment, thereby breaking the cycle between self-perceived stressed NQ and children's mental health (see Figure 2).

Figure 2. Breaking the cycle of environmental health disparities related to neighborhood quality and children's mental health.

OUR STUDY

Study subjects were participants in the Mothers and Newborns Study, a prospective longitudinal birth cohort at the Columbia Center for Children's Environmental Health (CCCEH). Between 1998 and 2006, CCCEH recruited 727 women ages 18-35 years into the study from the prenatal clinics of New York Presbyterian Medical Center, Harlem Hospital, or their satellite clinics [26]. Subjects were Dominican and African American women residing in Northern Manhattan (Washington Heights, Central Harlem) or the South Bronx. Enrollment exclusion criteria included smoking or use of other tobacco products during pregnancy, illicit drug use, first prenatal visit after 20th week of pregnancy, and the following pre-existing conditions: diabetes, hypertension, or known HIV infection. All study protocols were approved by the Institutional Review Board of Columbia University. Before each visit, mothers were informed about all study procedures and provided written informed consent to participate.

Neighborhood Quality (NQ) Assessment

When children were 5, 7, 9, and 11 years old, mothers were given a 32-question self-reported NQ assessment. The repeated administration of the questionnaire was intended to

evaluate patterns of NQ over time across middle childhood. The questionnaire was adapted from existing measures of NQ [27–29], and consisted of three subscales, each used to assess different subjective aspects of neighborhood composition. Subscales included social order/disorder (12 questions), safety and violence (seven questions), and social cohesion and neighborhood stability (13 questions). Content in the social order/disorder and safety and violence subscales was rated based on level of agreement (0-4), while components of the social cohesion and neighborhood stability subscale were evaluated through yes/no responses. Examples from each include “Homeless/unemployed people are hanging around” (social order/disorder), worried about “Letting children go outside during the day/night” (safety and violence), and “My neighborhood is a good place to live” (social cohesion and neighborhood stability). The full questionnaire can be found in the Supplemental File.

Anxiety and Depression Assessments

Anxiety and depression symptoms were assessed once in early adolescence when children were between 9-12 years.

RCMAS – Revised Children’s Manifest Anxiety Scale

The level and nature of anxiety symptoms in children were measured using the Revised Children’s Manifest Anxiety Scale (RCMAS), a self-administered 37-item assessment completed by the child. RCMAS is divided into three subscales including physiological anxiety, worry and oversensitivity, and social concerns and concentration. Answering “yes” indicates that the item is descriptive of the child’s feelings; higher scores on the assessment indicate increased levels of anxiety. Raw scores above 18 signal significant levels of anxiety that warrant further clinical assessment.

CDRS – Children’s Depression Rating Scale

Level and severity of depressive symptoms were measured using the Children’s Depression Rating Scale (CDRS) in a semi-structured interview administered by a trained research worker to the child. The CDRS includes 17 symptom areas encompassing cognitive, somatic, affective, and psychomotor symptoms. Examples include depressed feelings, difficulty having fun, depressed facial affect, and self-esteem. For 14 items, children rate on a 7-point scale, while the remaining three items are rated on a 5-point scale. Possible total scores range from 17-113. Any score above or equal to 40 signals significant levels of depression, whereas any score below or equal to 28 is often used to define minimal or no symptoms.

Statistical Analysis

There were $n = 727$ mother and child pairs with available data on self-perceived NQ gathered at any one of the assessing time points: child ages 5, 7, 9, and 11 years. Of 727, 379 children had available data on anxiety symptoms measured through the RCMAS, and 372 children had available data on depression symptoms measured through the CDRS (see Figure 3).

Figure 3. Flow Chart of Inclusion detailing how participants were selected for inclusion; parsimonious covariates include age at testing, sex, and ethnicity.

To analyze NQ, each participant's total NQ score and three individual subscale scores were standardized and scaled for the presence of stress. Items assessed through the 0-4 Likert scale were standardized such that all scores could be equally weighted and interpreted on a scale between 0-1 (0 = absence of stress, 1 = presence of stress). Subscale scores and total scores were found by taking the mean across all items. To analyze participants' patterns of NQ in middle childhood, group-based trajectory models using a latent class growth curve (LCGC) analysis were applied. Group-based trajectory models aim to identify clusters of individuals having similar NQ trajectories over the six-year period using finite mixture models [30]. We modeled total and individual subscale scores, varying numbers of groups (1–4) and shapes (linear, quadratic, cubic). We selected the best fitting model for each NQ outcome (total NQ, social order/disorder, safety and violence, and social cohesion and neighborhood stability) using the Bayesian Information Criterion (BIC), as well as the magnitude of group membership posterior probabilities. We evaluated change in BIC ($\Delta BIC \approx \log_e(B_{10})$) to compare increasingly complex models vs. the simpler (null) models and selected the final model based on the inflection point at which the ΔBIC leveled off [30, 31]. These analyses were conducted using the SAS Proc TRAJ macro [31]. Proc TRAJ will use any data provided to include the individual in the model that best fits them; individuals need not have all data points to be included.

To assess the association between patterns of NQ in middle childhood and symptoms of anxiety and depression in early adolescence, we examined eight multiple linear regression models, focusing on total NQ as our main exposure of interest. Prior to modeling, we assessed the distribution of RCMAS and CDRS to confirm that they were approximately normally distributed. NQ trajectory group was used as the independent variable, where separate models were fit to assess the association between total NQ, neighborhood social order/disorder, neighborhood safety and violence, and social cohesion and neighborhood stability and symptoms of anxiety (from RCMAS) and symptoms of depression (from CDRS) as the dependent variables. To isolate the effect of NQ on the presentation of anxiety and depression symptoms, we evaluated the inclusion of known or suspected risk factors for anxiety or depression symptoms based on the literature and our previous research [32]. These included sex, age (in months) of child at testing, ethnicity, mother's intelligence (measured by the Test of Nonverbal Intelligence 3rd Edition, TONI-3) [33], maternal education (completion of high school prior to birth of this child vs. no completion), and maternal demoralization (measured by the Psychiatric Epidemiology Research Instrument–Demoralization (PERI-D) scale) [34]. Final models included child sex, ethnicity, and age at testing, based on their statistically significant (at $p = 0.10$) association with either or both RCMAS and CDRS. Additionally, we explored stratified sex-specific associations between NQ and symptoms of anxiety and depression.

FINDINGS

A breakdown of participant characteristics is listed in Table 1. While there were no statistically significant differences among children included and excluded from this analysis, those included were slightly more likely to be female, African American, have lower maternal IQ and have mothers who were less likely to complete high school. At the time of enrollment, a majority of the participants resided in Northern Manhattan, a residential, non-tourist region of New York City that has been quickly gentrifying for the past 20 years [21, 35].

Table 1. Characteristics of subjects included (n = 386) and excluded (n = 342) from this analysis among 727 fully enrolled participants

Characteristic	Included in final model for CDRS or RCMAS (n = 386)	Excluded from final models (n = 342)	p-value
Sex (Female)	209 (54.1%)	167 (49.0%)	0.16
Race (African American)	146 (37.8%)	108 (31.7%)	0.08
Maternal Education (Completed High School)	233 (61.5%)	223 (66.8%)	0.14
Maternal TONI score ¹	20.0 (SD 8.6)	21.4 (8.8)	0.07
Maternal demoralization score ^{1,2}	1.16 (SD 0.64)	1.14 (SD 0.62)	0.68

¹ mean $\pm$ SD

² Range of demoralization: 0-3.3, where higher scores indicate more demoralization.

After total and subscale NQ data were standardized and scaled for the presence of stress, the best fitting group-based trajectory model yielded a binary separation of maternal self-reported NQ over the six-year assessment period in middle childhood. This result is shown in Table 2, where, for all four NQ outcomes, the two-group model showed the greatest change in

BIC when comparing between models with different number of trajectory groups. Thus, NQ results suggested two distinct groups of NQ patterns across middle childhood, namely persistently “stressed” over time and persistently “non-stressed” over time. Participant characteristics by total NQ group assignment are presented in Table 1. It is noteworthy that mothers who were categorized as living in more stressed neighborhoods are less likely to have completed high school ($p = 0.02$), have a lower TONI score ($p = 0.003$) and have more demoralization ($p = 0.009$) than participants in the non-stressed neighborhoods. Raw individual trajectories for total NQ are shown in Figure 4A, while mean total NQ values at each time point are presented in Figure 4B. Figure 4B also shows percent breakdown of the two groups, with 41% of mothers ($n = 158$) persistently rating their total neighborhood composition as stressed, and 59% of mothers ($n = 228$) rating their neighborhood as being non-stressed. While all subscales were correlated, the trajectory pattern of the neighborhood safety and violence subscale was most similar to that of overall NQ (see Figure 5).

Table 2. BIC and BIC change between different number of NQ trajectory groups

Number of Groups	BIC	Null Model	ΔBIC*
NQ (total)			
1	470.19		
2	726.79	1	256.6
3	768.84	2	42.05
4	787.28	3	18.44
NQ (social order/disorder)			
1	153.12		
2	369.11	1	215.99

4	44.76	3	11.83
NQ (social cohesion & neighborhood stability)			
1	-642.46		
2	-512.8	1	129.66
3	-485.84	2	26.96
4	-484.46	3	1.38

*BIC = Bayesian Information Criterion.

*ΔBIC: BIC change between a more complex model and null model.

We found that stressed NQ across middle childhood was not associated with any observable difference in anxiety symptoms in early adolescence (see Table 3). However, persistently stressed NQ was associated with higher levels of depression symptoms in this age group (see Table 3). After controlling for sex, ethnicity, and child age at testing, Figure 6 shows that children of mothers in the stressed NQ trajectory group scored, on average, 1.5 points higher on the CDRS than those in the non-stressed trajectory group—and this difference was statistically significant with $p = 0.046$ ($\beta = 1.56$, 95% CI: 0.03, 3.08). Although not statistically significant, it is notable that more individuals obtained CDRS scores greater than 40 (clinical cutoff) in the stressed versus non-stressed NQ trajectory group (10% vs. 6%, $p = 0.20$; Figure 6). None of the three NQ subscale trajectories were

individually predictive of children’s depression scores (data not shown), and we found no significant sex-specific associations between NQ and either anxiety or depression symptoms (data not shown).

Figure 4A. All individual total NQ trajectories across middle childhood revealing distinct separation between stressed and non-stressed trajectory groups.

Figure 4B. Total NQ trajectory grouping by mean showing percent breakdown between stressed and non-stressed trajectory groups.

Figure 5. Correlations between total and subscale neighborhood quality trajectories showing strongest correlation between total NQ and safety and violence subscale.

Figure 6. Difference in child report of depression symptoms between self-perceived stressed and non-stressed NQ as reported by mother.

DISCUSSION

In this study, we examined the association between longitudinal maternal self-reported NQ and children's self-report of symptoms of anxiety and depression. After controlling for other factors which may influence report of children's levels of symptoms of anxiety or depression, we observed that as mothers reported increasing levels of neighborhood stress, children reported increasing levels of symptoms of depression. Interestingly, while a number of sociodemographic factors were associated with NQ trajectory (e.g., education, IQ, demoralization), these were not significant predictors of child's report of depressive symptoms while self-perceived NQ trajectory was. Thus, maternal assessment of NQ may be an important predictor of childhood depression symptoms. Although we did not formally perform statistical tests of mediation, our findings support existing literature which suggests parent perception of NQ may act as a mediator between neighborhood environment and changes in children's mental health.

This research is relevant for the health and success of children living in stressed neighborhood environments. Depressive symptoms in childhood have been inversely associated with a child's ability to build social relationships, concentrate academically, and be self-reliant [36–38]. Understanding the environmental factors that drive children's symptoms of depression, including those related to NQ, is important as researchers continue to direct effort towards breaking the cycle of children's mental illness, particularly for those low-income and minority children who are more likely to live in disadvantaged neighborhood environments and more susceptible to poor mental health (see Figure 2). In order for such efforts to be best targeted, researchers must be able to acquire the most informative measurement of NQ as a predictor of children's mental health. The growing body of research proposing neighborhoods as a source inequality relies heavily on SES and its association with children's development [3]. Given the weaknesses inherent to Census collection data, these analyses might overlook important influences of neighborhood environment on children's health.

Rather than measuring objective neighborhood characteristics through Census, the self-reported NQ evaluation allows researchers to gauge neighborhood context and record how residents subjectively experience their surrounding environment. This is a useful tool considering that outside observation and resident perception of environmental stressors may not always converge [17]. Furthermore, the repeated, longitudinal administration of the self-report assessment allows researchers to capture the effect of quickly changing neighborhood characteristics on perception of NQ, which contrasts most NQ research based on neighborhood residence at a single point in time [12]. Thus, a subjective, long-term NQ assessment is more descriptive of the mechanisms through which a disadvantaged neighborhood environment may be linked to decreased mental health, and also better illustrates the mental, physical, and social dimensions that are known to shape a child's wellbeing [39].

These strengths of the self-report are particularly relevant as researchers analyze how gentrification impacts the health of existing low-income minority youth living in the neighborhood. This demographic is not only more likely to live in socially and economically

under-resourced urban neighborhoods, it may also be more vulnerable to inequitable neighborhood conditions due to ongoing transformation of urban communities [40, 41]. While direct effects of gentrification were not measured in this study, gentrification and its community health implications are interlaced in the context of our analysis. The children in this study live in Northern Manhattan, a neighborhood of New York City that has experienced rapid reinvestment. However, not all individuals residing in gentrifying neighborhoods, similar to this one, benefit from incoming resources. Using Census material to measure the benefits of reinvestment in a community may lead to the conclusion that gentrification is net positive for new and existing residents, as the data could reveal increases in median income and neighborhood diversity. Despite such socioeconomic changes, perceived neighborhood quality can remain constant for residents without access to the neighborhood's new amenities (e.g., upscale restaurants, commercial shopping districts), and also for residents displaced due to cost of living increase. In order to evaluate how certain children may benefit from gentrification disproportionately, a longitudinal, self-perceived NQ assessment is necessary. In future research, it may also be important to consider the role of large-scale public housing near or adjacent to gentrifying neighborhoods.

Study Limitations

There are a number of noteworthy limitations to this analysis, mainly related to our inability to control for all possible stressors that may contribute to a child's presentation of anxiety and depression symptoms, leading to residual confounding. While the children included in this analysis were not statistically different than those who were excluded due to missing data, there were slight differences that might have influenced the results (see Table 1). Additionally, some researchers have suggested differential effects on child behavior from two-parent and single-parent households [25], which leads us to believe that variances in family structure may also have affected children's symptoms of depression. Previous research conducted among this same cohort has shown that housing instability, as defined by more than three residential moves in a seven year time frame, is related to behavioral differences in childhood [42]. This provides an additional route for variance in children's mental development, one that can potentially be connected with gentrification and residential displacement in the future. Lastly, we recognize that we tested the effects of difference in NQ against two discrete endpoints—anxiety symptoms and depression symptoms. We did not adjust for multiple comparisons because there is independent literature suggesting investigation into both domains. Had we adjusted for multiple comparisons, our findings would not reach statistical significance with $p = 0.05$ due to the small sample size. Should researchers interpret this study as an exploratory, combined analysis between NQ and anxiety and depression symptoms, an adjustment for multiple comparisons would be necessary.

CONCLUSION

Through this study, we have shown that a mother's longitudinal assessment of her NQ is associated with her child's self-reported symptoms of depression in early adolescence. To

more closely connect gentrification to children's mental health outcomes, future research should connect gentrification indicators and precise resident location directly with changes in self-reported NQ. Through this linkage, researchers can document the disproportionate impacts to children that reinvestment can bring to urban communities. Furthermore, this information can be used to identify levers that can be used to develop health-based policy interventions designed to help all children living in gentrifying neighborhoods benefit from reinvestment.

ABSTRACT

Childhood lead exposure is associated with impaired cognitive development, decreased IQ levels, and increased rates of juvenile delinquency. Lack of access to municipal water services, which in some communities disproportionately affects Black neighborhoods, is associated with higher levels of lead in drinking water. Objectives: This study aims to characterize the effects of exclusion from municipal water infrastructure on childhood blood lead levels. Methods: We created a novel 16-year database of 34,314 children, with which we examined the effects of municipal water access on childhood blood lead levels in Wake County, NC. Using childhood blood lead data from 2002 to 2017, we used ordinary-least squares and logistic regression models with childhood blood lead levels as the primary outcome of interest and municipal water access at time of birth as the primary exposure of interest. Results: Our results suggest that a lack of access to municipal water is significantly associated with elevated blood lead levels. Children without municipal water service at birth had blood lead concentrations that were 0.12 µg/dL higher than children with municipal water. Children with access to municipal water service had significantly lower odds of having blood lead above the ‘level of concern’ as defined by the Centers for Disease Control than children with municipal water service (OR = 0.82). Conclusion: These findings support the need

for more regulatory oversight and water quality tests of private water systems or facilitating access to municipal supplies in order to mitigate the impacts associated with childhood lead exposure.

INTRODUCTION

Approximately 535,000 children ages 1 to 5 years in the United States had a blood lead level above 5 $\mu\text{g}/\text{dL}$ in 2018 [1]. There is no safe concentration of blood lead in children, and lead exposure in childhood has long been known to impair intellectual and behavioral development [2]. Young children are particularly susceptible to lead toxicity. Infants absorb 4 to 5 times more lead than older children and adults, and early childhood is a critical period of vulnerability to lead toxicity [3].

A lack of access to municipal water services is associated with elevated levels of lead in drinking water [4], especially among low-income and African-American neighborhoods [5]. “Municipal underbounding” is the phenomenon whereby communities of color living adjacent to majority white municipalities are systematically excluded from incorporation [6–9]. In the state of North Carolina, individuals outside of municipal service areas live in areas called extraterritorial jurisdictions (ETJs), and many of these households rely on private wells for water [10, 11]. It has been demonstrated that land use planning and policy, at least in some jurisdictions, has discriminatorily excluded low-income and minority neighborhoods from municipal boundaries [6, 8, 9, 12–14]. It has also been shown that race significantly predicts whether a community within an extraterritorial jurisdiction has municipal water services in North Carolina and Wake County, with predominantly Black neighborhoods being the least likely to have municipal water access [10, 11]. The Safe Drinking Water Act in the United States sets an action level for lead in drinking water at 15 $\mu\text{g}/\text{L}$. However, the Safe Drinking Water Act only applies to community water systems, which are defined as those serving at least 15 service connections or 25 people year-round [15]. Private wells, which are not protected by the Safe Drinking Water Act, are often overlooked as a source of lead exposure [4, 16].

The purpose of this project is to quantify the relationship between a lack of access to municipal water and childhood blood lead levels in Wake County, North Carolina, USA.

OUR STUDY

We created a database of 34,314 observations at the level of the individual child spanning from 2002 to 2017 with data including children’s blood lead, water access, location within an ETJ, demographic data, and other variables. Using this database, we used statistical models to estimate the effect of exclusion from municipal water services on childhood blood lead levels. Figure 1 illustrates the conceptual model used to create our statistical models.

Figure 1. Conceptual model detailing the causal pathway between lack of access to municipal water and a child's observed blood lead with key covariates which may also affect either water access or lead exposure, such as socioeconomic status or age of the home.

Database Development

Our retrospective database included tax parcel data from Wake County GIS Services, childhood blood lead data from North Carolina's Childhood Lead Poisoning Prevention Program (NC LEAD), and 2010 census data and 2017 American Community Survey (ACS) 5-year estimates data. NC LEAD provided all blood lead test results for children screened in Wake County between 2002 and 2017. The NC LEAD program requires health care providers across the state to report results of children's blood lead tests for surveillance purposes. While health care providers are encouraged to test blood lead for all children between the ages of 12 and 24 months, screening is mandatory for children enrolled in federal and state assistance programs (women, infants, and children; Medicaid; or Health Choice). The tax parcel data included in this study were for all residential parcels in Wake County from 2002 to 2018. All data cleaning and analysis was completed in STATA 15.1 (Statacorp, College Station, TX).

Merging all the yearly tax parcel files was the first step of creating the database. After acquiring the data, which is publicly available, we merged the yearly datasets using the unique PIN ID assigned to each parcel. If a parcel existed in multiple years of data, we kept the data for the first occurrence of the parcel, while incorporating all new parcel information that appeared in later years. Additionally, utility status and extraterritorial jurisdiction status were captured for each individual year for each parcel to determine when or if a parcel received municipal water access or if a parcel was incorporated into municipal boundaries. Utility data from Wake County GIS services, which indicated municipal water access, were only reported from 2002-2010. To capture data timepoints after this, we supplemented our data set with tax parcel data from Wake County's revenue services department from 2013 and 2018; additional years of data were not available. Therefore, municipal water access data were incorporated from 2002-2010, 2013, and 2018. After this, all non-residential parcels were dropped from the dataset, leaving only parcels identified as dwellings.

Next, childhood blood lead data from the NC LEAD database were merged with the tax parcel data using the addresses from both datasets. The addresses were disaggregated into their parts (i.e. street name and number, city, zip) and cleaned for any possible variations

between the two datasets (for example, RD versus road). We used an exact match on the datasets based on addresses, then STATA's DTALink function, which uses probabilistic linkage methods to score each potential pair of records on the probability the two records match, so that pairs with higher overall scores indicate a better match than pairs with lower scores. The merge parameters were iteratively revised and results reviewed until the parameters yielded results that included only exact matches and plausible inexact matches as determined from inspection of subsets of 100 matched entries.

Geocoding and Spatial Join

We used ArcMap (Version 10.6, ESRI, Redlands, CA) to geocode the data and perform a spatial join in order to merge ACS data to each observation. We geocoded the data in ArcMap using a stand-alone geocoding program created from ESRI's StreetMap Premium data for the year 2017 (StreetMap™ Premium for ArcGIS, ESRI, Redlands, CA). Fewer than 1% of the addresses were not matched; these were dropped from the dataset. We downloaded population demographics from the 2010 census and income data from the 2017 ACS 5-year estimates. We used a shapefile of Wake County to perform a spatial join to assign each observation from our dataset to a census block along with the corresponding census and ACS data.

Statistical Models

For the analysis of the database, the primary outcome of interest was childhood blood lead concentration, and the primary exposure of interest was municipal water access at time of birth. We built an ordinary least squares regression model and two logistic regression models using blood lead benchmarks of 5 µg/dL and 2 µg/dL. For all models, we controlled for age in intervals of 18 months, gender, municipal status at time of birth, year of blood draw, home value in logarithmic form, year the home was built, median household income at the census block group, percent Black population at the census block, and percent Hispanic population at the census block.

FINDINGS

A total of 34,314 children from Wake County, NC, were included in the analyses. The mean blood lead level for the population was 1.7 µg/dL, and the mean age of the child at time of testing was 550 days (see Table 1). Males and females were evenly represented at 51% and 49% of the study population, respectively. Approximately 5.5% of individuals in the study population lived in extraterritorial jurisdictions, and 14.7% of individuals did not have municipal water access at time of birth (see Table 2).

Table 1. Summary statistics for key continuous variables included in the models

Variables	Mean	Min	Max
Lead	1.65	1	35

	N	32,443	94.5
Gender	F	16,827	49
	M	17,487	51

Variables Influencing Blood Lead Levels in the Study Population

Access to municipal water and Black race were associated with children's blood lead levels (see Table 3). Children without municipal water service at birth had blood lead concentrations that were 0.12 $\mu\text{g}/\text{dL}$ higher than children with municipal water. Blood lead levels increased, on average, by 0.023 $\mu\text{g}/\text{dL}$, for every 10% increase in the Black population proportion in the child's census block. In contrast, Hispanic population was not associated with blood lead levels. Year the child was tested was highly significant ($p < 0.0001$), with each additional year of time being associated with a decrease in blood lead levels of -0.092 $\mu\text{g}/\text{dL}$.

Similarly, the age of the child being between 18 to 36 months was highly significantly associated with an average increase in blood lead of 0.13 $\mu\text{g}/\text{dL}$ from the referent (less than 18 months, $p < 0.0001$), and the age of the child being between 36 to 54 months was also significantly associated with an average increase in blood lead of 0.095 $\mu\text{g}/\text{dL}$ ($p < 0.05$). Year the house was built was also highly significant at all levels when compared to the referent (built before 1950), with houses built between 2000 and 2005 being associated with the lowest level, a decrease of 0.55 $\mu\text{g}/\text{dL}$ blood lead ($p < 0.0001$). Finally, home value in logarithmic form was highly significantly associated with a decrease of 0.22 $\mu\text{g}/\text{dL}$ in blood lead level on average for every log-10 increase in home value ($p < 0.0001$). Thus, a two-fold increase in home value is associated with a decrease in blood lead levels of -0.066 $\mu\text{g}/\text{dL}$.

Each point represents the odds ratio, and the lines extending left and right from each point represent the lower and upper confidence intervals, respectively.

Variables Influencing the Odds of Elevated Blood Lead Levels in the Study Population

Children with access to municipal water service had significantly lower odds of having elevated blood lead above the 'level of concern' as defined by the Centers for Disease Control than children with municipal water service (see Table 4, Figure 2: OR = 0.82, $p < 0.05$). Similarly, these children had decreased odds of having blood lead concentrations above 2 µg/dL than children without water service (see Table 5, Figure 3: OR = 0.73, $p < 0.0001$). Year in which the child was tested was highly significantly associated with the odds of elevated blood lead levels when dichotomized at 5 µg/dL (see Table 4, Figure 2, OR = 0.81, $p < 0.0001$). The same effect was observed when blood lead was dichotomized at 2 µg/dL (see Table 5, Figure 3, OR = 0.78, $p < 0.0001$). Children living in census blocks with increasing fraction of Black population had significantly higher odds of elevated blood lead levels when dichotomized at 5 µg/dL (see Table 4, Figure 2, OR = 1.5, $p < 0.05$). Similarly, children living in census Blocks with increasing fraction of Black population had highly significantly increased odds of blood lead levels above 2 µg/dL (see Table 5, Figure 3, OR = 1.8, $p < 0.0001$).

Children living in census blocks with increasing percentage of Hispanic population did not have significantly increased odds of having elevated blood lead levels above 5 µg/dL (see Table 4, Figure 2, OR = 0.58, $p = 0.23$). However, when dichotomized at 2 µg/dL, children living in census blocks with an increasing fraction of Hispanic population did have significantly increased odds of having blood lead levels above 2 µg/dL (see Table 5, Figure 3: OR = 1.5, $p < 0.05$).

DISCUSSION

The objective of this study was to characterize the effects of exclusion from municipal water infrastructure on childhood blood lead levels in the community studied. We found that

municipal water access and childhood blood lead levels are significantly associated across all models in this dataset. Children without municipal water access were more likely to have elevated blood lead levels as compared to children with municipal water access in the area studied. These findings support our hypothesis that a lack of access to municipal water is associated with elevated blood lead levels in our study population.

The findings of this study lend support to the hypothesis that private well water in underserved communities may contribute to the risk of elevated blood lead. Studies have found significant amounts of lead from private well water in neighborhoods without municipal water access in North Carolina [5]. To date, this is the first study seeking to determine the relationship between a lack of municipal water access and childhood blood lead levels. Multiple studies have described racial disparities in municipal water access in North Carolina [8, 11, 13, 17, 18] and Wake County specifically [10]. Predominantly Black communities in this area are significantly less likely to have municipal water access [10]. Our results further these studies' findings by providing evidence that Black communities are also more likely to have elevated blood lead levels.

It is also important to consider the historical context of race in drawing municipal boundaries and providing municipal services in some communities. Predominantly Black communities have been historically excluded from municipal boundaries in some jurisdictions [6, 8, 13, 18]. The results of this study suggest potential health risks associated with being excluded from municipal boundaries by increased blood lead levels due to unregulated private wells, especially for predominantly Black communities. Health effects from lead exposure in childhood include decreased IQ, poor school performance, and increased risk of delinquent behavior [2]. The severe and pointed effects of childhood lead exposure are still an issue today, and drinking water constitutes a major source of lead exposure in some communities.

The findings of this study have many implications for public health and urban planning policy. Our results demonstrate a clear relationship between childhood blood lead levels and municipal water access. The results of this study demonstrate a clear relationship between demographics at the census block level and childhood blood lead levels. This demonstrated relationship in Wake County, while not generalizable to other locations, could be used by municipalities to determine which neighborhoods are most likely to benefit greatly from municipal water extensions.

Cycle of Childhood Environmental Health Disparities

Lead exposure in childhood is one example of persistent environmental health disparities experienced more frequently by communities of color. Figure 4 shows the cycle of childhood environmental health disparities experienced by communities without access to municipal water infrastructure. Children living in underbounded communities without access to public drinking water infrastructure rely on private wells, which are unregulated under the Safe Drinking Water Act. Public water systems governed by the Safe Drinking Water Act are required to implement corrosion controls to prevent the leaching of lead into the water supply, but private wells do not have these protections [15]. Corrosive ground water from private wells can cause lead to leach from well and plumbing components [19].

Figure 4. The cycle of childhood environmental health disparities experienced by individuals excluded from municipal water services due to racial underbouding of their community.

Households that rely on private wells are likely to neither have the knowledge nor the means to monitor water quality and/or to maintain their water systems should an issue be discovered [20–23]. Thus, children living in these communities without access to municipal water infrastructure are at a greater risk for elevated blood lead levels, as demonstrated in this study’s results. A report published by the CDC found blood lead levels of Black and Hispanic children were elevated compared to the blood lead levels of white children [1]. Lead exposure in childhood results in negative health outcomes such as neurotoxicity, learning disorders, and behavioral problems, even at low levels of exposure [24–26]. To break this cycle of childhood environmental health disparities, targeted interventions must be implemented to better educate private well owners on the importance of testing water quality regularly and implementing corrosion controls. Additionally, policy makers should work with historically underbouded communities to facilitate the extension of municipal water infrastructure.

Baltimore, Maryland, USA

ABSTRACT

Living in poverty has detrimental effects on children's health. Children who are resilient may be protected from the damaging health effects of a low-income environment. There is a moderate amount of literature suggesting exercise behaviors can increase resilience. In this study, we investigate whether college students from low-income environments with established childhood exercise habits are more resilient than students who exercised less. An electronic survey sent to students at the University of Massachusetts, Amherst included the Brief Resilience Scale[®] to measure students' resilience levels and the Godin Leisure-Time Exercise Questionnaire[®] to measure current and past exercise habits. The final analysis included 269 responses. Across income brackets, participants exercise most frequently in high school and least frequently in college. Students in the lowest household income bracket exercise the least while students from the highest household income bracket exercise the most. Students in the high-medium income bracket had the lowest mean resilience scores, and students in the highest income bracket had the highest resilience scores. When controlling for other variables, college exercise was shown to predict increased resilience scores. Additionally, middle school exercise was shown to predict high school and college exercise. These results demonstrate the necessity of interventions to increase exercise in children from

* Corresponding Author's Email: mhowett@umaryland.edu.

low-income environments, establish exercise habits early in childhood, and use exercise as a strategy to promote resilience. Such interventions may enable children to protect themselves from developing chronic diseases caused by their environmental circumstances and thus break the cycle of environmental health disparities.

INTRODUCTION

Living in poverty has detrimental effects on children's health – children from low-income households have an increased risk of developing behavioral disorders [1] and developing a chronic disease later in life compared to children from higher income families [2]. The list of possible underlying causes of these conditions is extensive – studies identify pollution [3], food insecurity [4], poor housing quality [5], lack of access to recreational space [6] and healthcare providers [7]. These factors highlight the environmental health disparity between children from low-income households compared to average or high-income households. In order to mitigate the potential damaging health effects of poverty and break the cycle of health disparities, children need to have tools to manage increased stressors of their environment and cope with the adverse effects.

Frequent exercise has been shown to be one method that allows children to manage stress and improve their mental health [8]. Since children in low-income environments experience higher stress levels [9] they may greatly benefit from using exercise to overcome the challenges of their harsh surroundings. Unfortunately, children from low-income households exercise significantly less than their wealthier peers [10]. Research has identified a lack of access to recreational spaces [11], inadequate sports facilities [12] and unsafe neighborhood conditions [13] as possible causes of this disparity. The impact of children's physical environment on physical and mental health has become a highly researched subject, and the relationship may be more complicated than previously thought. For example, Huynh et al. [14] showed that children who reside near highways have a two-fold increased risk of uncontrolled asthma compared to children living more than two miles from a highway.

Developing resilience to the harsh environmental conditions associated with living in a low-income household would allow children to protect themselves the long-term damaging effects of asthma and other environmentally triggered conditions. The American Psychological Association [15] defines resilience as “the process of adapting well in the face of adversity, trauma, tragedy, threats or significant sources of stress.” In a 2014 review of literature on the subject of resilience, Southwick et al. [16] describe psychological resilience as complex construct with determinants that include “a host of biological, psychological, social and cultural factors that interact with one another to determine how one responds to stressful experiences.” Studies have shown these factors to include emotional intelligence [17], self-esteem, number of adverse life experiences, and quality of parental relationships [18].

In this study, we measure the resilience of college students from different backgrounds and examine the role of past and present exercise habits as a factor in their resilience level. Based on literature that demonstrates the role of exercise in reducing stress and the protective nature of resilience [19, 20], we hypothesize that established exercise habits will increase the resilience levels of children from low-income environments and bring them closer to breaking the cycle of health disparities (see Figure 1). We decided to measure exercise habits over time

in addition to current exercise patterns because we felt measuring long-term habits would yield an understanding of when interventions focused on exercise would be most effective in increasing resilience. Additionally, none of the previous literature on this subject explores the impact of long-term exercise habits and family income on resilience in college students specifically. Thus, our study will address this gap in the literature and yield a better understanding of how long-standing exercise habits impact college students' resilience levels and how family income impacts this relationship.

Figure 1. Hypothesis of the role of established exercise habits in breaking the cycle of health disparities.

OUR STUDY

This study was conducted at the University of Massachusetts (UMass), Amherst, a large four-year public institution. UMass Amherst is an appropriate setting for conducting this research due to the diverse student population; approximately one out of five students in the 2018 entering class are first generation college students and 15% of students are from underrepresented minority groups [21]. After approval by the University's Institutional Review Board, a 23-question, five-minute, online electronic survey was developed using RedCap®, a HIPPA-compliant survey software. To recruit participants, the survey link was sent to 13 professors to forward to their class lists, posted on two class Facebook® pages, and verbally presented to students in three lectures halls at the beginning of that day's lecture.

Questionnaire

A single electronic survey was developed by combining the Brief Resilience Scale®, three iterations of the Godin-Shephard Leisure-Time Exercise Questionnaire® and participant demographic questions. Results from the Brief Resilience Scale allow researchers to assess respondents' resilience as "ability to bounce back from stress" and assign a unitary construct to resilience with as few queries as possible [22]. This scale was chosen because it is a

concise yet reliable method of quantifying resilience [22]. The Godin-Shephard Leisure-Time Exercise Questionnaire[®] is a self-reported survey of weekly instances of mild, moderate, and strenuous leisure time exercise [23]. In order to examine how exercise habits change over time, researchers included the survey three times, asking students about their exercise frequency in middle school, high school, and college. In addition to its high reliability and validity [24], the Godin-Shephard Leisure-Time Exercise Questionnaire[®] was chosen because it can be used to calculate a weighted exercise score based on the type of exercise. Researchers agree with the creator of the scale who states that the ability to weigh exercise by type provides a more comprehensive description of participants' exercise habits than scales that do not account for the type of exercise [23]. Additionally, both questionnaires produce numerical results which were used for quantitative analysis.

Demographics

Demographic questions included age, gender, academic grade level, family household income, financial aid status, parental education level, and ability to cover household expenses. Yearly family household income was broken into four brackets: high (\$200,000 or more), high-medium (\$150,000-\$199,999), low-medium (\$60,000-\$149,999), and low (less than \$60,000). These brackets were created to straddle the average family household income of a UMass Amherst student, which is \$120,000 [25]. Each of these income brackets is significantly above the national poverty level; researchers chose the income brackets so the sample would be evenly distributed in order to make reliable conclusions about exercise and resilience for each group of respondents.

Resilience

Resilience was measured using the Brief Resilience Scale[®] developed by Smith et al. [22] in 2008 (Cronbach's alpha from .80 - .91 over four samples). This scale was chosen over the more extensive resilience scales in order to promote completion of the entire survey and increase the number of valid responses. The scale includes three positively worded statements such as "I tend to bounce back quickly after hard times" and three negatively worded statements such as "I have a hard time making it through stressful events" [22]. Students respond to these statements on a Likert scale from Strongly Disagree to Strongly Agree. Based on responses to these statements, a resilience score was assigned to each participant on a scale from one to five.

Exercise Habits

Long-term exercise habits were measured using a modified version of the Godin-Shephard Leisure-Time Exercise Questionnaire[®] [23]. Independent evaluations of the scale have shown it to have satisfactory validity and reliability checks against gold-standard measures of physical activity [24]. The original scale asks how many times per week

participants perform mild, moderate and strenuous exercise at one point in time. The scale was modified and repeated three times, asking students about their exercise habits in middle school, high school, and college. To calculate a weighted exercise score for each time period, moderate exercise weekly instances were multiplied by two, and strenuous exercise weekly instances were multiplied by three and added to the other types of exercise. Additionally, a total exercise score was calculated by adding the weighted sums from the three time periods.

Data Analysis

After the data collection period, quantitative statistical analysis with multiple regression was performed on SPSS software version 25[®] [26]. A total of 300 surveys were submitted by participants. 31 surveys were not included in the analysis because respondents did not fill out the survey to completion. Resilience and exercise scores were averaged for participants in each of the four income brackets to examine correlations with income. For multiple regression analysis, a *p*-value of 0.05 was used to determine the statistical significance of relationships between demographic variables, resilience score, and exercise at each time period.

FINDINGS

Of the 269 surveys included in the final analysis, 73.2% percent of participants were female and 26.8% percent were male (see Table 1). Most participants (70.6%) reported receiving some form of financial aid. The largest group of participants (38.8%) were college juniors. Additionally, the largest group of respondents (42.8%) was in the low-medium income bracket. Most participants (71.4%) reported that one parent had at least a bachelor's degree (see Table 1 for demographic information).

The distribution of mean exercise scores in middle school, high school, and college by income bracket is displayed in the graph titled *Exercise by household income level in middle school, high school and college* (see Figure 2).

Across all income brackets, participants exercise most frequently in high school and least frequently in college. Exercise frequency was positively correlated with income level in all three time periods. Students in the lowest income bracket exercise the least in middle school, high school, and college, while students from the highest income bracket exercise the most. In addition to exercise, resilience was also lower among students in the lowest income bracket than the resilience of students in the highest bracket, but overall the relationship between income and resilience was not linear. Students in the high-medium income bracket had the lowest resilience scores. Mean resilience scores by income are displayed in the graph titled *Mean Resilience Score by Income level* (see Figure 3). The graph titled *Sum of individual exercise scores compared to individual mean resilience scores* shows participants' total exercise score (the sum of their weighted scores in middle school, high school, and college) compared to their resilience score (see Figure 4). While there is a large amount of variability in the results, there is a slight positive relationship between exercise and resilience. Multiple linear regression analysis showed that, when controlling for all other variables, exercise in

college correlated with students' resilience score. Additionally, middle school exercise was shown to strongly predict high school exercise and moderately predict college exercise.

Table 1. Participant demographics

Variable Label	N	Percent
Gender		
Female	197	73.2
Male	72	26.8
Age		
19	45	16.7
20	95	35.3

DISCUSSION

The purpose of this study was to measure whether childhood exercise habits impact the resilience of college students from different income levels. Respondents were divided into four income brackets. Students' resilience scores and weekly frequency of mild, moderate, and vigorous exercise levels in middle school, high school and college were analyzed. Trends and positive correlations in student's resilience and exercise seen in this study are consistent with current literature and can be used to make recommendations to increase resilience through exercise. The primary finding that college exercise was predictor of resilience in this dataset adds weight to the existing literature demonstrating a connection between exercise and resilience. The significance of this finding is increased by the fact that the largest percentage of participants were college juniors, who, by the third year of college, may have more

consistent habits than freshmen. Although some students may have left the university by Junior year, 86.6% of UMass Amherst Juniors were retained from the original freshman class [27]. The relationship between frequent exercise and increased resilience can be used to support the implementation of exercise programs targeted towards increasing resilience and improving mental health of college students. The finding that students who exercise in middle school continue to exercise in high school and college reveals exercise habits are established early in life and is consistent with literature on the subject. Thus, we recommend interventions for children across income levels should begin with introducing exercise at a young age since the habit will likely be maintained in young adulthood and beyond.

While individual interventions are important, local and national governments should also recognize the impact of environmental improvements on exercise outcomes of entire communities. A greenway built in Knoxville, Tennessee significantly increased the amount of time community members spent walking and biking [28], although other studies show that trail users are most likely to be white adult males [29]. Among children from low-income households in Chicago, perceived neighborhood safety was associated with the amount of unstructured play while access to neighborhood exercise facilities predicted organized sport participation [30]. Healthcare policy advocates should refer to case studies and literature that demonstrates the impact of green space, recreational facilities and safe neighborhoods on children's health to promote policies that improve the built environment.

When controlling for other variables with multiple regression analysis, family income and other socioeconomic variables did not significantly predict resilience or exercise. Although student demographics did not predict exercise habits in the data, there was a positive correlation between exercise and income level. This finding is consistent with the robust literature demonstrating the disparity in exercise habits of children in low and high-income environments [31]. Trends in resilience by income were less linear – students in the high-medium income bracket had lower resilience scores than students in the two lower income brackets. Studies of childhood development and stress have shown that experiences of severe adversity, called ACEs (Adverse Childhood Experiences), have long-term destructive effects on children's physical and mental health [32]. However, experiencing a moderate amount of adversity (as the students in the lower income levels most likely have) can contribute to the development of resilience [33]. In a longitudinal survey of 1,994 participants, Seery et al. [33] found that respondents with a history of some lifetime adversity were less affected by adverse experiences than individuals with an extensive history of adversity or no history of adversity. Seery et al. [33] hypothesized that experiencing some adversity could “teach effective coping skills, help engage social support networks, create a sense of mastery over past adversity, foster beliefs in the ability to cope successfully in the future, and generate psychophysiological toughness” [33]. The beneficial effect of moderate adversity can be compared to the common belief that strenuous exercise and sports “build character” [34]. The literature on exercise and adversity suggests exercise may be a form of intentionally induced moderate adversity that creates a similar effect to the moderate stress described by Seery et al. [33]. Further research should be conducted to compare the impact of experiencing purposeful, positive adversity through exercise to the impact of experiencing unfortunate adversity such as ACE's. Exercise may provide an opportunity for children to safely experience hardship and failure to develop psychological resilience that becomes vital when more serious challenges arise.

At the Mindfulness-Based Stress Reduction Clinic, located a short drive away from the UMass Amherst campus, students can learn resilience not only on the sports field, but also in a classroom. Participants practice mindfulness techniques which demonstrate that "paying attention on purpose, in the present moment, and nonjudgmentally, to the unfolding of experience moment to moment" can even help to manage physical conditions such as asthma, fibromyalgia, skin disorders and heart disease [35]. This approach stresses the relationship between physiological habits and mental health. This mind-body relationship suggests that both physical and psychological training through exercise, meditation, and mindfulness, are important elements in fostering resilience for individuals of all ages.

Limitations

Limitations of this study include the fact that the sample ($n = 269$) was relatively small, and from only one public university. The ethnic distribution of participants was representative of the UMass student population (see Figure 5), but due to the sample size the number of participants from minority groups was too small to be able to make conclusions about exercise and resilience of different ethnic groups. Additionally, students were mostly recruited from traditional lectures in disciplines such as computer science, business administration, nursing, biology, and engineering. Including students studying art, dance, or agricultural studies may be underrepresented because they do not attend traditional lectures and were therefore harder to recruit for this study. The unequal gender distribution of the sample (73.2% female) is likely due to the fact that one of the lectures researchers attended to recruit participants was a Nursing lecture and included mostly female students. In order to encourage completion of the entire survey, demographic questions were kept as concise and simple as possible, which may have resulted in loss of detail about students' backgrounds.

Figure 5. Race distribution of UMass student population versus study sample.

Because participation was optional, the study population was self selecting, so results do not necessarily reflect information about other college students. The relatively high household income of the study population limits the study's generalizability. Future surveys should include an analysis of a more diverse sample as well as other socioeconomic variables in addition to income. A deeper exploration of students' lifestyle would be valuable – one suggestion is to ask students if they have to work to finance their education or pay back large student loans. Additionally, a longitudinal study that follows a cohort over time would be more accurate than retrospective responses. Finally, different methods of quantifying exercise habits, including real-time activity monitors such as watches or chest straps, would be useful to remove the inaccuracies of the self-reports used in this study.

CONCLUSION

Through a self-selected survey of college students, psychological resilience levels, family household income, and past and present exercise habits, student's exercise frequency was determined to predict students' resilience and that students who start exercising in middle school are likely to continue exercising in high school and in college. Results also showed household income level is directly related to how much a student exercises. The finding of a correlation between the low resilience and the poor exercise habits of children from low-income households shown in this study suggests exercise interventions should be targeted towards children in low-income environments to help them build resilience to the health risk factors that are prevalent in these environments. Furthermore, the relationship between exercise and resilience shown in this study should prompt health policy changes to improve children's environments making exercise accessible and safe in the critical middle school years, thereby promoting protective resilience against environmental stressors. Resilience built through holistic interventions that include consistent physical and psychological training will enable children to disrupt the cycle of health disparities resulting in improved health, educational achievement and success in life.

INTRODUCTION

Adolescents grow up in a digital environment which promotes and at the same time threatens the development of their bio-psycho-social well-being [1]. Teens in the United States in 2015 on average spent one hour and twenty minutes playing video, computer, or mobile games [2]. Another study found that they spent about 6 hours a day in 2016 on digital media and social media [3]. New media, including computer games and social media, is an important part of adolescents' daily experiences. From a positive view, we need to develop more digital game-based learning (DGBL) materials to promote the wellbeing of young people through self-help and peer influence. However, a majority of adolescents' favorite

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

commercial games usually involve violence and pornographic content. Moreover, there are concerns that computer game use puts adolescents at risk of addiction, violence, sexual exploitation, exposure to hateful or discriminatory contents, online and offline victimization, social isolation, and so on.

Game-Based Learning for Positive Youth Development: A Preventive Approach

Games have a long history as they can promote bio-psycho-social well-being for all ages. Parents, teachers, social workers, and mental health practitioners may use different types of games, including chess, board, card, physical, mental and spiritual activities, and video/digital games for educational purposes. The design and use of digital games in education developed together with the rise of home computers. Prensky [4] first coined the term digital game-based learning (DGBL). Since then developers have produced educational games according to educational theories to enhance engagement and learning outcomes. However, the number of educational digital games can hardly compare to that for entertainment purposes. While the controversy of possible ill-effects of many digital games is still on-going, the rapid development of new technologies facilitates the design and production of digital games that hold potential for education, medical and health, humanities and social sciences, and many more disciplines. Charities and non-profit making organizations that support bio-psycho-social-cultural well-being are becoming aware of the effectiveness, efficiency, and potential contributions of digital games to their causes and social impact. They contributed to supplementing the gap left behind by commercial companies. As part of the effort in promoting positive youth development (PYD) among early adolescents, seven digital games were designed and developed to support the Project P.A.T.H.S. which has been recognized as an evidence-based intervention by World Health Organization for ending violence against children [5] and promoting life and social skills in adolescents [6]. These games will strengthen the intervention strategies in prevention at primary, secondary, and tertiary levels. This special issue will focus on theory, practice, and initial evaluation of these digital games designed for the enhancement of PYD (hereafter referred to as DPYD games).

Prevention

As an interdisciplinary field to address the need for prevention-related research, numerous studies in prevention science have demonstrated with increasing evidence that many antecedents of risk behaviors can be prevented. They also support that primary and secondary prevention is much better than tertiary prevention because they save lives, minimize harms of different kinds, reduce public expenditure on expensive remedial treatment of risk behaviors, promote positive development, and build a better environment for children and adolescents. The latest development in prevention science witnesses the development and evaluation of DGBL.

Digital Game-Based Learning (DGBL)

This trend suggests that DGBL will become one of the major teaching and learning strategies in prevention, particularly in education [7-9], health fields [10-12], social-emotional learning [13-14], and treatment, for example, of children with attention-deficit/hyperactivity disorder [15]. The presence of digital games in promoting social-emotional learning (SEL) and positive youth development (PYD) is spreading due to their favorable results in terms of intended learning outcomes and users' engagement [16].

Many studies have examined the negative impact of playing video games, such as addiction, aggression, interruption of sleep habits, and parent-child conflict. Only a few studies have investigated potential positive outcomes [17-18]. However, very few studies demonstrate a link between playing video games and enhanced well-being, problem-solving skills, intergroup relations, and physical activity [10, 19-21]. This special issue is an effort to explore further the impact of DGBL on PYD.

ADOLESCENT ISSUES AND DIGITAL POSITIVE YOUTH DEVELOPMENT GAME: A CONCEPTUAL FRAMEWORK

We are now living in a digital age. Many children and adolescents and their parents keep using their smartphones and computers day and night. It is very difficult, if not impossible, to trace the effects of smartphones and social media on adolescents although it seems that the effects are potentially profound [1]. Rapid changes in the contexts of varied exposure to media contents, playing on-line games, connection with different on-line groups, post challenges and create opportunities for adolescents. From developmental and preventive perspectives, we are concerned about how adolescents handle their developmental tasks in the digital era with regard to the fact that their bio-psycho-social-cultural-behavioral interactions with family and peers have been changed drastically as compared to that of their parents. We may even agree that with the rapid development of information and communication technology (ICT), substantial contextual changes in the environment of adolescents could take place in months, based on Moore's law [22] that the speed of the central processing unit of a computer will double while the price will go down about every two years.

The uses and gratification approach in explaining how adolescents use and are affected by the use of smartphones and new media is far from adequate because its assumption on individual characteristics and decisions are convincingly confronted by Kahneman's Nobel Prize winning study on irrational judgment and decision-making in times of uncertainty [23]. Bronfenbrenner's [24] perspective on interactions between different social spheres is well-accepted to guide studies on media effects on adolescents. Based on Bandura's social learning theory and Gerbner's cultivation theory, Steele and Brown's [25] media practice model which covers personal identity, characteristics, daily practices, and the environment is a more specific approach to examine the factors for the media to induce various effects on adolescents.

Why These Games?

When focusing on early adolescents (aged 12-15 years), we witness changes in the following ways:

1. disrespecting others, engaging in dishonest, criminal on-line behaviors, and cyberbullying partly due to a wrong conception of anonymity in the cyber world;
2. being confused in building one's own identity partly because of premature decisions based on irrational judgment and decision-making [23] as well as information explosion;
3. experiencing difficulties in bonding with parents partly due to the use of "electronic pacifier", the lack of parental attention and quality parent-child time as a result of over-use of smartphone and social media [26], and in relating to peers as a result of weakened communication skills and emotional development [27];
4. having gender stereotypes and biases partly due to the biased advertisements and media contents; and
5. emphasizing money and success in cultivating their value systems partly because of media exposure.

As a prevention measure, seven digital positive youth development (DPYD) games were designed and developed. By strengthening relevant PYD constructs, these games target at enhancing the players' competencies.

SEVEN DIGITAL GAMES FOR PYD: A BRIEF DESCRIPTION

With the support by the sponsor, the seven DPYD games introduced in this special issue were designed mainly for the promotion of five core competencies among the 15 PYD constructs identified in successful programs by Catalano et al. [28], namely, social (SC),

Table 1. Adolescent issue addressed and targeted PYD constructs of each game

	Name of the Game	Adolescent Issue Addressed	Core PYD Constructs	Related PYD Constructs
1	The Digital Age	Respect for privacy	Moral Competence, Social Competence	Resilience
2	The Integrity Crisis	Integrity	Moral Competence, Social Competence	Resilience
3	The Bullying Storm	Bullying and cyber-bullying	Moral Competence, Social Competence	Resilience
4	The Male-Female Dichotomy	Gender stereo-types and biases	Clear and Positive Identity	Self-determination, Prosocial Norms, Social Competence, Moral Competence
5	The Great Thinking Adventure	Cognitive traps	Cognitive Competence	
6	A Journey to Somewhere, to Someone	Friendship and love affair	Bonding, Social Competence, Behavioral Competence, Emotional Competence	Self-Determination, Clear and Positive Identity, Prosocial Norm
7	Live a Meaningful Life	Money and success	Spirituality	Self-efficacy

cognitive (CC), emotional (EC), moral (MC), and behavioral competencies (BC) as well as the following seven constructs, namely, clear and positive identity (ID), self-determination (SD), self-efficacy (SE), bonding (BO), resilience (RE), spirituality (SP), and prosocial norms (PN) among adolescent users of these games. Only three constructs were not included—promotion of beliefs in the future (BF), providing opportunities for prosocial involvement (PI), and recognition for positive behavior (RP). Although DPYD game design must provide immediate positive feedback and reinforcement of RP and PI at the cognitive and intention levels, responses in playing DPYD games are not actual behaviors. Table 1 shows the name, adolescent issues addressed, and targeted PYD constructs of each game.

OVERALL AIMS

This book covers a collection of seven digital games as a demonstration of the state-of-the-art non-commercial “serious games” [9, 29] for promotion of PYD among adolescents. The design of each game and how it can be creatively used by teachers and professionals to achieve the purposes of primary, secondary, and to a smaller extent, tertiary prevention are presented. An early female adolescent studying in an international school in Shanghai and a 19-year-old male college student in the United States were invited to play all the games and provide detailed comments on their learning experiences. Their insightful comments and feedbacks are presented. Difficulties in the use of DGBL technologies will also be discussed, although technical issues in game development are omitted. Some chapters also address implications for ongoing research that will further our knowledge of how DPYD games affect youth development. The use of distinctive game design principles and elements (e.g. rules of play, point scoring, competition with others, immediate feedback) in promoting PYD are discussed in chapter 2.

This book has demonstrated the design and development of DPYD games which show the practice of permeation of gamification [10] and the application of game design principles into positive youth development through e-learning and as a supplement to the conventional learning procedure as a future emergence.

Theory and Practice of Using DPYD Games for Prevention

In this book, chapter 2 offers a thorough discussion on theory and practice of design, development, and use of digital games for the enhancement of PYD constructs. Education theories, concepts and knowledge of gamification, GBL, game principles, and DGBL are reviewed to provide theoretical underpinnings to support the development of these seven games. It also discusses the importance of enabling young people with relevant knowledge and skills to handle commonly found issues properly.

Furthermore, this introductory chapter discusses how and why the creative use of these games will serve the purposes of prevention. For primary prevention, it is to protect adolescents from engagement in risk behavior and harm. These DPYD games are designed for early adolescents (S1 to S3, Grades 7-9) in English, traditional Chinese and simplified Chinese. For secondary prevention, the DPYD games provide guidance and feedbacks

according to users' responses to some relevant and valid psychosocial measures. Adolescents who experience some problems in one or more of these common issues could benefit from the feedback generated according to their choices in a number of carefully selected psychosocial tests. It is particularly useful when students are encouraged to use the print-screen function to keep the feedback and reply to the game using different strategies or available options. Learning can be consolidated when students compare and contrast different outcomes or results with their choices during different stages and at the end of the game. For tertiary prevention, adolescents who suffered from problems in these common issues could be helped by using selected parts of the game as initial engagement, assessment, and part of the intervention efforts to be jointly discussed and determined by the target user and the professional. Although the games do not keep any personal or psych-social test data on the computer in order to protect users, users can use the print-screen function to capture the results and feedback generated. With the consent from users, the print-outs can be used for engagement, raising target users' awareness of the issues and their responses to difficult situations, conducting initial diagnosis, and serving as topics for discussion on the use of knowledge and skills provided in the game to handle similar situations or crises.

Finally, chapter 2 contributes to the development of a practice model named "STREAM" to promote PYD through digital games for prevention.

The Design of Three Games on the Same Theme

Chapter 3 discusses how game design knowledge is applied in the first three games and how they can help adolescents who face difficulties with on-and-off-line interpersonal relationship difficulties, including intruding into someone's privacy, following peers' dishonest behavior, and engaging in bullying and cyber-bullying with peers. The three short DPYD games, each runs for about 15-20 minutes, serve as a series of games on the same theme using three different stories.

Seven Chapters on Seven Games

The following seven chapters each offers a review of a specific and current adolescent issue. Each chapter demonstrates how teachers and professionals can use the specially designed game to promote core competence and related PYD constructs. Concrete suggestions on how to use the game creatively and effectively are presented. Each chapter is supported by theory and users' critical comments as initial qualitative evidence. Theoretical and practical issues are discussed, and limitations and future research suggestions are presented.

The Use of Literature in a DPYD Game

Chapter 11 contributes to cross-disciplinary methodology in illustrating the use of literature in the design and development of a DPYD game. It provides a significant reflection

on the nature and function of literature and its importance in promoting PYD constructs among adolescents.

SPECIFIC OBJECTIVES

The chapters in this book tackle questions related to GBL and PYD. The newly developed games target knowledge acquisition and the development of qualities that are PYD friendly. In this issue, we explore how these games can be used to help adolescents acquire knowledge and skills such as self-awareness, moral decision making, perspective-taking, empathetic understanding, acceptance and respect of gender difference, avoidance of cognitive fallacies, effective communication, personal reflection, relationship building and maintenance, handling intimate relationships, and in managing their own finances as part of their game playing experiences. Moreover, we try to explore how these games can be used to support greater insight into the process and effectiveness of PYD and how they can be effectively used for the prevention of problems encountered by adolescents. In this collection of papers, we seek to

- review the literature on a range of contemporary developmental challenges and relationship issues;
- review the literature on game-based learning for PYD with an intention of preventive intervention;
- describe how these games can serve as additional resources to support the existing teaching and learning materials of the project P.A.T.H.S. to enhance its effectiveness;
- provide users' qualitative reviews on each game to identify their strengths and weaknesses;
- discuss issues related to gamification of PYD, in particular, to consider how user agency, gamification, transportation theory, learning theories, perspective-taking, communication, the use of literature, the integration of in-person individual and group counseling, and other factors that may affect the intended outcomes of these games; and
- develop further questions, practice guidelines, and recommendations for establishing preventive programs around using digital games to enhance PYD.

To achieve these objectives, the seven chapters on each game contain four parts. First, it presents a review of relevant literature on selected contemporary adolescent developmental issues. Second, it gives a description of the game design, contents, objectives, and its relation to the project P.A.T.H.S. by detailing concrete teaching points with relevant concept maps. Third, it offers a discussion on identifying critical success factors after a presentation of the users' feedback and the viewpoints of implementers. Finally, a discussion on intervention strategies via the digital game is included to offer insights and direction for future game development and research.

METHODOLOGY

A significant portion of the chapter on each game is devoted to the implementation and initial evaluation. To demonstrate the effectiveness of the games, the qualitative approach was adopted according to five dimensions that were used in the literature review:

- *Participants*: Convenient samples were used. Two participants, a 15-year old female student from Shanghai and a 19-year old male college student from the United States were invited. For the female participant, parental consent was secured.
- *Intervention*: Participants played the games in their leisure at home.
- *Methods*: For all games, no time limit and number of testing moments were set.
- *Outcome measures*: Free expression in written format. No word limit was set.
- *Data-analysis*. Reflective writings of participants were used for illustration.

CONCLUSION

On the whole, this special issue furnishes a rich description and discussion on the theory and practice of DPYD games, in particular, design, implementation, and initial evaluation. Chapters in this book show a concerted and creative effort in providing preventive measures on commonly found adolescent developmental issues. They also demonstrate that the newly developed and specially designed games are in general efficient and effective measures to promote PYD and prevent some common adolescent problems from deteriorating in contemporary urban societies. Initial users' qualitative feedback supports their effectiveness. Findings related to motivational variables such as self-efficacy, situational interest, goal orientation, and engagement variables are discussed. It is noteworthy that the game on interpersonal relationship has a special feature of promoting cross-cultural understanding of the values behind Chinese and Western (English-speaking only) cultures.

Future effort is needed to improve the measurement of DPYD game use as well as conduct longitudinal research on the effects of DPYD games to identify if and how cumulative effects could result from the use in the presence of a multitude of important variables, under what circumstances and in what developmental stages.

ACKNOWLEDGMENTS

The design and production of the seven digital games introduced in this book, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This book is based with permission on papers adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

Chapter 346

THE ‘STREAM’ MODEL OF DIGITAL GAME-BASED LEARNING FOR ENHANCING POSITIVE YOUTH DEVELOPMENT AMONG ADOLESCENTS

Tak-Yan Lee^{*}, PhD

Department of Social and Behavioral Sciences, City University of Hong Kong,
Hong Kong, PR China

ABSTRACT

To help adolescents develop 21st century skills, digital game-based learning (DGBL) is an effective option. Supported by learning theories and game elements in designing DGBL, more and more “serious educational games” (SEGs) have been produced. Results of evaluation studies provide evidence of the effectiveness of DGBL and expand the literature to cover new areas such as positive youth development (PYD), and peaceful and sustainable societies. To promote PYD, digital positive youth development (DPYD) games could be a cost-effective option. This chapter offers a review of learning theories and digital game design elements that show the design and development of DPYD games as effective learning resources. Guided by learning theories and game elements, this chapter describes how seven newly developed games can help promote relevant PYD constructs among adolescents, clarify their values, and enhance their knowledge and skills to handle properly difficulties commonly encountered, and to protect them from being harmed and engaging in risky behaviors. Finally, based on theories and initial users’ feedback, this chapter attempts to enhance the literature through the development of a practice model from the prevention science perspective to guide future practice.

INTRODUCTION

The aim of this chapter is three-fold. First, it provides a brief review of literature on the theory and practice of design, development, and the use of digital game-based learning

^{*} Corresponding Author’s Email: ty.lee@cityu.edu.hk.

(DGBL) for the enhancement of positive youth development (PYD) constructs. Educational theories, concepts, and principles of DGBL were reviewed to provide theoretical underpinnings to support the design and development of seven digital positive youth development (DPYD) games.

Second, it briefly describes the design of these seven games and how they can be used as electronic learning materials for the prevention of common adolescent issues. They are intrusion of privacy in digital and real-life environments, participation in dishonest behaviors due to peer pressure, engagement in bullying and cyberbullying (BCB) in on-and-off-line situations, demonstration of gender biases and stereotypes, confinement in cognitive fallacies, having difficulties in friendship and romantic relationships (FRRs) as well as improper attitude towards money and success.

Third, it presents a model to guide the practice of prevention through the creative use of these DPYD games among early adolescents at three levels – primary, secondary, and tertiary. Specifically, this chapter

- reviews the literature on DGBL for enhancement of PYD as prevention;
- describes a range of contemporary developmental challenges and relationship issues;
- describes how the games can serve as digital resources to promote PYD;
- discusses issues related to DGBL of PYD constructs, in particular, gamification, game-based learning, learning theories, perspective-taking, communication, the use of literature, the integration of individual and group counselling, and other factors that may affect the intended learning outcomes (ILOs) of these games; and
- presents a practice model of using DPYD games for prevention purposes.

LITERATURE REVIEW

Games play an important role in human history as they are essential parts of being alive [1-6]. Educational games have a long history as they can promote bio-psycho-social-spiritual well-being. Parents, teachers, social workers, and mental health practitioners may use different types of games, including chess, board, card, physical activities, and video/digital games for educational purposes. Gamification is the application of game-design elements in different contexts including education [7, 8]. It aims at improving user engagement, learning, feedback to users, and more. Game-based learning has huge market potentials [9].

Computer Game

Prensky [10] classified eight “genres” of digital games—action, adventure, fighting, puzzle, role-play, simulation, sports, and strategy games. Recently, Bean [11] classified eleven genres of digital games—action, action-adventure, adventure, horrors, racing, shoot-’em-ups, simulations, sports simulations, strategy, role-playing, and others. Although there is a wide range of cultural genre of computer games, Martin [12] summarized five communities through co-citation analysis. They are education, humanities/social sciences, computer science, communication, and health. The rapid advancement in information and

communication technology (ICT) proliferates the production of computer games mainly for entertainment purposes. Unfortunately, many of them have various degrees of violence and pornographic content.

Digital Game

After Prensky [10] published the first book on digital game-based learning (DGBL), increasing efforts have been made in developing digital games or “serious games” for education, medical and health, and bio-psycho-social-cognitive-behavioral rehabilitation that fit roughly into the framework of prevention science. From 2006, thousands of research studies on digital games were published every year [12, 13].

Digital Game-Based Learning (DGBL)

Digital game-based learning (DGBL) refers to achieving an educational purpose through the use of fun/entertainment means [10, 14, 15]. The range of research on DGBL covers all ages of learners [16], examination of its relationship with 21st century skills [1], identification of best practices [17], development of educational games [1], building up models [18, 19], and assessment of its effectiveness of interventions for prevention, treatment and rehabilitation purposes [20-23]. Recent efforts have been devoted to the establishment of a comprehensive methodology [24] and platforms for the interdisciplinary design of games in education [25, 26].

Types of DGBL

Two types of games can be distinguished in DGBL: special-purpose games that have been developed with an educational purpose and commercial-off-the-shelf games that have been developed for entertainment purposes but deployed in an educational context [27]. This chapter focuses on purpose-built educational games that strike a balance between gaming elements and learning for non-commercial purposes [28]. On the commercial side, the latest products of popular digital games show a trend of combining different genres, for example, *League of Legends*, *Minecraft*, *Counter-Strike: Global Offensive*, *Tom Clancy's Rainbow Six: Siege*, *World of Warcraft*, and *Hearthstone: Heroes of Warcraft*. New technologies including 5G, artificial intelligence (AI) and virtual reality (VR) will enlarge the functions, create more opportunities, and enhance the attractiveness of DGBL. For educational purposes, they are usually called “serious games” or “serious educational games” (SEGs) [14, 21, 24, 29].

Examples of Game-Based Prevention Programs

Some GBL programs are designed for prevention. Examples include preventing child sexual abuse among children aged 8 to 10 years [30], obesity among children [31], fire

prevention education among children [32], phishing prevention among regular computer users [33], and car accident prevention for drivers [34]. The newly developed DPYD games are the latest examples of such intent.

Merits and Demerits of DGBL

An increasing number of studies has demonstrated positive outcomes of DGBL which include enhancing students' enthusiasm in learning [35], providing an exciting avenue for learning [36], meeting students' emotional needs [37], and enhancing their problem-solving skills [38]. However, DGBL may contribute to other forms of addiction which include gambling, addiction to technology [39], and prolonged screen time [40, 41].

Learning Theories and Successful Game Designs

While commercial digital games employ “every single worthwhile learning theory in existence” [42], studies on GBL point out a lack of theory support [43, 44]. For example, a review of 567 published studies found a close connection between the use of learning theories and positive outcomes but most studies fail to discuss the application of learning theories [44].

Learning theories have been enriched by anthropology, communication, psychology, socio-linguistics, and sociology. Classical learning theories include behavioral theory [45] and social learning theory [46]. Experiential learning theory [47] and self-determination theory [48] belong to the humanistic approach which stresses that each student should be respected as a unique individual who is capable of learning in his/her own style and pace. Cognitivism emphasizes that learning depends on mental capacity and stresses that a free environment for decision-making is vital. Distributed cognition [49] and cognitive theory [50] are the most relevant to GBL.

The constructivist perspective which includes social constructionism [51] and social constructivism [52] theorizes how human beings construct their knowledge through active processes. While social constructivism emphasizes an individual's learning from his or her interactions in a group, social constructionism [51] focuses on the products that are co-created through social interactions in the group. Constructivism theories that are highly related to GBL include cognitive apprenticeship [53], communities of practice [54], activity theory [55, 56], and situated learning theory [23].

Contemporary learning theories that can also explain DGBL include generative learning [19, 57], flow theory [23, 56], and narrative centered learning [58]. Last but not least, uses and gratification theory [59] helps to design and use digital games as prevention tools because no GBL can happen without engagement or motivation.

Theories for Digital Game-Based Learning

This section will briefly describe how these theories support DGBL. When playing DPYD games, students learn by doing tasks and are benefited through *experiential learning*.

If learners fulfill their innate psychological needs of competence, relatedness, and autonomy, they will function and develop at an optimal level according to *self-determination theory* [48, 60].

Although stand-alone and collaboration games require different strategies, the former removes the pressure of social comparison to reduce or eliminate social stigma and sanction during the learning process. Collaboration games require social interaction. Through *distributed cognition*, i.e., sharing cognitive resources, players can achieve learning outcomes that an individual learner cannot achieve alone [49, 61]. When engaging or sharing the tasks or strategies of a game with peers, they form a community of practice through which they interact regularly to improve their performance [54].

Activity theory helps explain the achievement of intended learning outcomes (ILOs) because digital games allow players to participate and experiment in non-threatening situations and learn through the game repeatedly to maximize learning effects [55, 56]. The theory provides a framework that explains a hierarchical analysis of motivated human activity [62]. To achieve pre-determined ILOs, game-based learning is designed in a given context or setting, providing specific information and knowledge, and requiring special skills. In this connection, *situated learning theory* provides substantial support as it emphasizes that an individual learns, sees, and behaves in his/her role within society [63]. The game provides game-based learning environments that integrate educational information and interactive scenarios with gameplay dynamics to boost players' motivation. This is what *narrative-centered learning* refers to [64]. From the players' point of view, *uses and gratification theory* suggests that students control their media usage instead of just being influenced by the games or media [65].

When designing a DPYD game, *cognitive apprenticeship* is helpful as it stresses the importance of turning the tacit processes into an open-mode, through which students can learn with the help from the "master of skill" [53]. Flow theory helps us understand the mental state of the game-player who fully concentrates and engages in the activity when doing something that challenges his/her skills [66].

Game Design Elements for Digital Game-Based Learning

DGBL and gamification are similar in that they both promote engagement and sustain intrinsic and extrinsic motivations in learning. They can be distinguished in that DGBL involves applying game elements in designing new learning activities that are intrinsically game-like to achieve learning outcomes whereas gamification applies game design elements to existing learning activities. A review of the literature identifies 22 digital game design elements. The summary presented below draws on the extensive analysis by Qian and Clark [1]. Table 1 shows the simplified definitions of game design elements. These 22 elements are used to evaluate the seven DPYD games and the results are presented after an introduction of the games.

Table 1. Definitions of game design elements

	Game Element	Definition
1	Challenge	An element which enhances the difficulty of the game [50], for the purpose of providing active learning experiences to players [67]
2	Collaboration	Providing players with a situation to work together with others in handling a challenge [68] through which players learn and internalize knowledge when they respond to others during the discussion [69]
3	Competition	As an interactive feature of the game which allows a player to play against the computer, another player or his/her own records [19, 70]
4	Complexity	The situation that balances the features of games and simulations of real-life conditions [57] and provides different pathways for players toward the goal [58]
5	Control	The power to influence or direct the learning and thinking of players [71]
6	Exploration & Discovery	An inquiry-based learning activity in which players think and explore the situation so as to boost their critical thinking abilities [72]
7	Goals	A desired result of the game which requires players to try a variety of methods for reaching it [23] and a crucial element for efficient learning games since it enhances the motivation among players [50, 56]
8	Interactivity	Providing interactive learning opportunities for players [73] so as to boost their development of scientifically appropriate responses to different situations [58]
9	Low Stakes Failure	Allowing players to improve technique and decisions by trial-and-error through pleasantly frustrating experiences [70]
10	Narrative	Referring to the storylines, conditions and characters of the game [74] which help attract the players to devote their full attention and experience situations and emotions brought by the interactions with the characters of the game [58]
11	Realism	The imitation of a realistic situation in the game [19]
12	Role Play	Assigning each player to be a character in the dramatic interactive story with the responsibility to complete the tasks by choosing how the story can go on [75, 76]
13	Rules	Providing players with a rule-based environment for the purpose of making the game engaging and fun [23, 50]
14	Scaffolds	Acting as supporting equipment for the balance of the game contents and educational contents [77]
15	Self-Expression	Providing chances for players to control their learning process so as to enhance their learning confidence and motivation [78]
16	Strategy	A detailed plan which requires players' communication, strategic thinking, and problem-solving skills [67, 68] for achieving the final goal of becoming competent at playing games [79]
17	Surprise & Uncertainty	The situation when an unexpected condition happens which raises the comprehension of the game by requiring players to reevaluate the preconceptions of the game [80]
18	Immediate feedback	Improving players' problem-solving skills and enhancing their sense of achievement [55] by determining whether the players' solution in the game is correct [81]
19	Augmented reality (AR)	A three-dimensional interactive experience of the real-world environment and computer-generated objects, in which players can interact with each other in real-time [69]
20	Curiosity	Acting as an element that raises players' motivation in engaging in the game [82]
21	Explanation	The interpretation of the social flow experience [50, 56]
22	Rewards	Providing the scores and ranking of the game, which boosts players to accomplish the tasks set in the game [69]

USING DIGITAL GAMES FOR PROMOTING POSITIVE YOUTH DEVELOPMENT (PYD)

The rapid development of new technologies facilitates the design and production of digital games with potentials for educational purposes in disciplines such as education,

medical and health, humanities and social sciences, and many more. The use of digital games in education has a long history. However, the number can hardly compare with that of commercial games for entertainment purposes.

With the support of a funder, the seven games introduced in this special issue were designed mainly for the promotion of five major PYD constructs, namely, social (SC), cognitive (CC), emotional (EC), moral (MC), and behavioral competencies (BC). They can also enhance clear and positive identity (ID), self-determination (SD), self-efficacy (SE), bonding (BO), spirituality (SP), and prosocial norms (PN) among adolescent users of these games. Table 2 shows the name, the adolescent issue addressed, and targeted PYD constructs of each game.

Table 2. Adolescent issues and PYD constructs addressed by the seven DPYD games

	Name of the Game	Adolescent Issue Addressed	PYD Core Competence	Related PYD constructs
1	The Digital Age	Respect for privacy	MC, SC	RE
2	The Integrity Crisis	Integrity	MC, SC	RE
3	The Bullying Storm	BCB	MC, SC	RE
4	The Male-Female Dichotomy	Gender stereotype and biases	BC	ID
5	The Great Thinking Adventure	Think critically and discern wisely	CC	
6	A Journey to Somewhere, to Someone	FRR	SC, BC, EC	SD, ID, BO, PN
7	Live a Meaningful Life	Money and success	BC	SP, SE

Five Themes

The major contents of the seven games can be grouped into five themes, namely, “online and offline interpersonal relationship” (three games); “gender stereotypes and biases” which covers appearance, behavior, occupation, and trait; “think critically and discern wisely” which focuses on cognitive fallacies; “friendship and romantic relationship” (FRR) as well as “money and success.” These themes are chosen because of their relevance to the lives of adolescents in most urban cities. Figure 1 shows the relationships between the issues and the games.

Figure 1. The relationships between adolescent issues and the DPYD games.

Table 3. The intended learning outcomes and related PYD constructs of each game

Name & Issue	Intended Learning Outcomes			PYD Constructs
	Cognitive	Emotional	Behavioral	
1. The Digital Age: Respect for privacy	- understand: - the boundary of privacy; - the need to deal with privacy issues in an honest and careful manner; - the need to respect the privacy of others; - the different ways to tackle bullying - reflect on the choice between friendship and honesty; - understand the necessity of sincere confession; - be aware of different ways of handling threats from classmates	Change from understanding the victim's plight (pity), to caring for the victim (sympathy), and to showing compassion for (empathy) the victim's pain and negative emotions.	- consciously practice honest behaviors; - take appropriate actions to deal with interpersonal conflicts; - reduce the behaviours of escalating bullying incidents; - prevent the worsening of bullying incidents	MC, SC, RE
2. The Integrity Crisis: Integrity	- reflect on the choice between friendship and honesty; - understand the necessity of sincere confession; - be aware of different ways of handling threats from classmates	Change from understanding the victim's plight (pity), to caring for the victim (sympathy), and to showing compassion for (empathy) the victim's pain and negative emotions.	- consciously practice honest behaviors - refuse to perform inappropriate behaviors - take appropriate actions in face of frauds or extortions - do good deeds to their friends - proactively admit one's fault - forgive a friend's wrong doings	MC, SC, RE
3. The Bullying Storm: Bullying and cyber-bullying	- understand - school bullying; - the need of adherence to important personal principles; - the need to seek assistance actively if necessary; - various ways of dealing with bullying - understand their own gender stereotypes and biases in "appearance", "behaviour", "occupation" and "traits"	Change from understanding the victim's plight (pity), to caring for the victim (sympathy), and to showing compassion for (empathy) the victim's pain and negative emotions.	- take appropriate action to deal with interpersonal conflicts; - seek help proactively from the teacher or good friends in face of bullying; - reduce the behaviors of escalating bullying incidents; - prevent the worsening of bullying incidents	MC, SC, RE
4. The Male-Female Dichotomy: Gender stereotype and biases	- understand the 51 cognitive traps; - understand the principles of rational thinking; - enhance the capacity for identifying the cognitive traps; - understand the effective use of thinking ability - understand the personal traits and characteristics of oneself; - learn gender equality and beware of gender issues; - differentiate the levels of friendship and identify features of good friends; - distinguish like from love; - understand the 14 important elements of building, maintaining, and enhancing friendship; - understand the seven stages of love affair	enhance their acceptance of the opposite gender in four areas	- reduce discrimination against people with a distinctive gender profile; - get along harmoniously with the opposite gender as a result of an increased acceptance level	BC, ID
5. The Great Thinking Adventure: Cognitive traps	- understand the 51 cognitive traps; - understand the principles of rational thinking; - enhance the capacity for identifying the cognitive traps; - understand the effective use of thinking ability - understand the personal traits and characteristics of oneself; - learn gender equality and beware of gender issues; - differentiate the levels of friendship and identify features of good friends; - distinguish like from love; - understand the 14 important elements of building, maintaining, and enhancing friendship; - understand the seven stages of love affair	reduce emotional distress in daily life caused by mistakes made	use thinking ability to help others	CC
6. A Journey to Somewhere, to Someone: Friendship and romantic relationships	- understand the 51 cognitive traps; - understand the principles of rational thinking; - enhance the capacity for identifying the cognitive traps; - understand the effective use of thinking ability - understand the personal traits and characteristics of oneself; - learn gender equality and beware of gender issues; - differentiate the levels of friendship and identify features of good friends; - distinguish like from love; - understand the 14 important elements of building, maintaining, and enhancing friendship; - understand the seven stages of love affair	- feel the joy of a reciprocal relationship with friends or partners - reduce negative emotions resulting from relationship problems with peers and partners	- increase desirable behaviors related to strengths of one's personal traits; - reduce undesirable behaviors related to weaknesses of one's personal traits; - get along harmoniously with the opposite gender; - identify and make desirable friends; - practice empathy; - learn active listening; - understand and try effective ways to deal with conflicts; - apply knowledge and skills to handle issues arising from a love relationship	BO, SC, BC, EC, SD, ID, PN
7. Live a Meaningful Life: Money and success	- understand their own view and practice of financial management; - reflect on the values and meaning of life	- enhance their EC in facing life issues beyond their control; - enhance their levels of empathetic competence and care for the community through experiencing the lives of different social classes	apply prudent financial management skills	BC, SP, SE

Intended Learning Outcomes

The cognitive, emotional, and behavioral ILOs of these seven games are described in Table 3.

USING GAME ELEMENTS IN DESIGNING DPYD GAMES

Different game elements were used in designing the seven games. Table 4 shows an initial assessment of the use of 22 game design elements in each of the game. It only represents the views of the author and the main designer of these seven DPYD games. High (H), Medium (M), Low (L), and None (0) were used to indicate the relative strengths.

Table 4. The level of game design elements used in each game

Game Design Element		Use of Game Element in the 7 Games						
		1	2	3	4	5	6	7
1	Challenge	M	M	M	M	H	H	M
2	Collaboration	M	M	M	0	M	H	H

TOWARDS A PRACTICE MODEL OF USING DPYD GAMES FOR PREVENTION

Effectiveness studies on DGBL focus on two core elements – player engagement/motivation and achievement of ILOs [14], which are also the two major issues – theory and practice – that inform the design and application of DPYD games. The first issue

emphasizes the need for the application of learning theories and game design elements. To achieve ILOs, purpose-built DPYD games must be underpinned by learning theories and game design elements. This chapter gives a brief description of why and how traditional and contemporary learning theories can be applied in designing DPYD games. Moreover, this chapter reviews and provides precise and concise definitions of game design elements which are then used to assess how well these elements are adopted in the seven newly-developed DPYD games. As a necessary condition for effectiveness, these games must motivate students to use the game preferably more than once and they must be more than fun to engage users. As described above, 22 game design elements have been used to engage and motivate target users. The effectiveness of these elements in motivating and engaging target users remains unknown. Future research is needed in this area.

The second issue is the development of a practice model that guides the appropriate use of these seven purpose-built DPYD games for effective prevention. To help teachers and mental health practitioners to make good use of these games, a practice model is presented below. Supported by learning theories, the model is named 'STREAM,' an acronym which is the abbreviation of the following components:

- (1) Scope: Using the games for prevention at primary, secondary, and tertiary levels;
- (2) Tool: Selection of appropriate DPYD games/relevant parts of a game;
- (3) Reward systems: Creation and maintenance of reward systems to promote the appropriate use of the feedback generated according to players' choices and responses;
- (4) Educational processes: Enhancement of players' independent, collaborative, and supportive learning in an environment conducive to deep learning;
- (5) Assessment of learning outcomes: Collection of users' formative and summative feedback;
- (6) Mixed methods of research for innovation: Creating prospects for transformational advance in DGBL to promote PYD.

The STREAM model offers professionals a framework for helping adolescents address common issues and prevent problems by changing their attitudes, knowledge, skills, and behaviors through DGBL. It offers prevention strategies for adolescents, who may encounter intra- and inter-personal problems, with two main pillars of education – learning to be and learning to live together [83]. This model incorporates educational principles and knowledge into strategies to help adolescents prevent problems by promoting relevant PYD constructs. It is believed that this model is equally applicable to other DPYD games. The contents of the practice model are presented below.

The Scope: Enhancement of PYD for Prevention at Different Levels

This set of DPYD games is useful for prevention in primary, secondary, and tertiary levels. For primary level, it aims at preventing users from involving in risky behaviors or getting harmed. For secondary level, these games can benefit adolescents who have experienced mild challenges for some common adolescent problems by providing them with

feedback based on their responses. Regarding tertiary level, students who have these problems can be helped by being encouraged to play relevant games or using specific parts of a game for engagement, initial assessment, and as part of the intervention plan.

Although the games will not save any personal or test data to safeguard privacy, students can be invited to use the print-screen function to keep the feedbacks. The feedbacks can be used for conducting an initial assessment, promoting self-understanding, monitoring their reactions to different conditions, equipping them with skills in handling similar situations in real-life, and documenting changes. For example, to prevent BCB, the first three games can be used. At the primary level, the games can be used in class in which students are asked to choose one of the responses either by casting a vote or inviting one representative to make the choice. To enhance learning, the games can be available for students who have gone through the debriefing after the demonstration. In secondary level, the game can be introduced to a group of selected students who experienced BCB problems in different roles – the bully, the victim, and the bystander. The game helps the professional build up trust and a working relationship with group members, diagnose, and change members' beliefs and behaviors. For tertiary level, the professional may use the game for helping the target students practice assertive behaviors (SC and BC), enhance empathetic understanding (BO and MC), promote self-understanding (SE), and foster resilience (RE).

The Tool: Selection of Appropriate DPYD Games/Relevant Parts of a Game

Most of the seven DPYD games provide branch-out stories that promote curiosity and replay modular [84]. Students can try alternate routes to create an atmosphere for discussion to promote curiosity and maximize learning. The game 'A Journey to Somewhere, to Someone' also allows for multiple entry points at secondary and tertiary levels. Careful selections of the most appropriate entry points which meet the needs of the target players to facilitate learning are important.

Reward Systems: Creation and Maintenance

Reward systems foster intrinsic motivation, promote players' positive and appropriate behaviors, and engage players in learning through the PDYD game [85]. Aside from the built-in reward systems in the game, the creation and maintenance of reward systems to promote the appropriate use of the feedback generated from the game according to players' choices and responses are also important. For example, the games about on-and-offline interpersonal relationships provide six choices that affect how the game story develops and the feedbacks the player receives. Instructors can create a new reward system by making use of the feedback to encourage the player to replay in order to compare the results of different strategies or choices. Alternatively, after reflecting on the contents of 'Character trait' through discussion, instructors may encourage students to set goals for improving the scores of some desirable traits. They can compare and contrast different results by using the print-screen function to boost their learning. Besides, students can try different roles in each scenario to understand the consequences of different choices at the end of the game. This may facilitate students to

put themselves in others' positions. Furthermore, choices are crucial for adolescents according to self-determination theory of motivation [48]. The variety of DPYD games is, in fact, a motivator as they provide choices. Furthermore, the availability of choices during the game serves to engage the player. For example, the design of the first three games about on-and-offline interpersonal relationships provides six choices based on the five communication modes [86].

Educational Processes: Independent, Collaborative, Supportive, and Proactive Learning

For *independent* learning, students are given a DPYD game to play on their own. Motivation and engagement are crucial for self-learning. For *collaborative* learning, students can be encouraged to join a discussion with their peers after playing the game. Instructors may also encourage them to play together with peers to stimulate interactions and discussion to maximize the achievement of the ILOs. For *supportive* learning, instructors can guide students to discuss their experiences so as to consolidate their learning. Instructors can also encourage students to play DPYD games more than once. Moreover, learning is highly effective when learners are motivated, capable of mastering the content knowledge, and practice what they have learned. Instructors may use the 4F techniques (facts, feelings, findings, future) [87] to engage students, promote curiosity as well as encourage a change in strategies and choices when replaying the game. For example, when using the game 'The Great Thinking Adventure,' to facilitate *proactive learning*, instructors may encourage capable students and help them organize competitions or even design the contents for the 51 cognitive traps according to the definitions and examples provided. This approach can benefit more students by updating the contents of the game and create an ethos for the school to enlarge the impact.

It must be added that the learning environment is also vital for learning processes to take place effectively. To enhance PYD among adolescents through adopting purpose-built digital games, a relaxing environment should be provided when instructors introduce and demonstrate how to play the games before students work on their own. It helps raise students' interests and motivations.

Assessment of Learning Outcomes

While DGBL can primarily aim to achieve specific ILOs, it could also achieve secondary learning outcomes [88]. For example, the game 'A Journey to Somewhere, to Someone' with a primary aim to promote FRRs (social-emotional-moral-behavioral outcomes) can also result in a more accepting attitude towards taking literature as a subject (cognitive learning outcomes).

Although the potential for using DPYD games for targeted, curriculum-driven teaching and learning and self-directed learning is enormous, many well-intentioned games have failed to achieve their ILOs [89]. A systematic collection of users' feedback on how well ILOs have been achieved is necessary.

Mixed Methods of Research for Innovation

It is important to create prospects for transformational advance in DGBL to promote PYD through the use of mixed methods of research for innovation. While teachers and practitioners must involve in collecting users' evaluative feedback, researchers should also involve them in conducting quantitative research to test hypotheses and collect formative feedback to improve the game design.

CONCLUSION

This chapter is an attempt to deal with the practice of prevention with the adoption of DGBL. It briefly reviews learning theories and game design elements to illuminate the learning processes and the linkage of theory and practice. Its contribution lies in explaining how DPYD games can be used in the prevention of some commonly-found adolescent issues. Application of DGBL technology and innovation can play an important role to promote PYD. This chapter also makes an initial attempt to generalize some aspects of the theory and practice of DPYD games. It provides a practice model that attempts to integrate learning theories and game elements in the design and application of DPYD games for prevention. Readers will find revised definitions of game design principles (Table 1) that are necessary for further development of the DPYD games.

While this chapter provides initial answers to some application questions by proposing a practice model, some issues need more attention. First, we need to find more resources to develop DPYD games. Second, most professionals who help adolescents are not well-informed of the available DPYD games and their potentials. Some may never have a chance to play such games [89]. Promotion of the efficacy of DGBL and how it can enhance PYD for prevention is needed. Third, we need more research to inform the development of DPYD games and support further game-enhanced prevention. At the same time, we need to know the limitations [90].

ACKNOWLEDGMENTS

The design and production of the seven digital games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by The Hong Kong Jockey Club Charities Trust. Readers may request free copies for non-commercial purposes of these games by contacting Dr TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

Chapter 347

DESIGNING DIGITAL POSITIVE YOUTH DEVELOPMENT GAMES FOR THE ENHANCEMENT OF ON-AND-OFFLINE INTERPERSONAL RELATIONSHIPS AMONG ADOLESCENTS

Tak-Yan Lee*, PhD

Department of Social and Behavioral Sciences, City University of Hong Kong,
Hong Kong, PR China

ABSTRACT

To prevent conflicts in peer relationships (PRs) which are commonly found among adolescents, a set of three digital positive youth development (DPYD) games has been developed and made available free of charge for non-commercial and educational use. These games aim to enhance the core competencies of adolescents in handling PRs so as to prevent bullying and cyberbullying (BCB). This chapter describes the design and functions of these three games - 'The Digital Age', 'The Integrity Crisis', and 'The Bullying Storm' which share the same game structure. In these games, students follow different storylines, encounter difficult online and offline situations, and have to choose a response out of six choices in each scenario. Based on students' responses, their patterns of the use of conflict management strategy and their relative strengths on each of the twenty positive psychological constructs will be presented in the form of a percentage at the end of the game. With proper guidance by instructors, these games can help students learn how to handle on-and-offline PRs and BCB. Finally, this chapter discusses issues related to the use of game principles in designing DPYD games and using them for prevention.

* Corresponding Author's Email: ty.lee@cityu.edu.hk.

INTRODUCTION

Adolescents often encounter problems with on-and-offline peer relationships (PRs) partly due to the high penetration rate and the inappropriate use of smartphones [1-3] and the internet. In many cases, such problems may end up in bullying and cyberbullying (BCB). Besides, many adolescents grow up in families with few or even without siblings. This means that children and adolescents are in lack of appropriate experiences in interacting, playing, giving and receiving social and emotional support, arguing, fighting and resolving conflicts with siblings. The lack of effective parental supervision and guidance is also a risk factor for adolescents having troubles in their PRs. In 2013, *the Time Magazine* first coined the term the “*Me Me Me Generation*”, which is characterized as over-protected, overly-recognized, and narcissistic adolescents [4]. A reason leading to this phenomenon may be that people starting in the 1970s wished to boost children’s chances of success through enhancing self-esteem, but they accidentally raised their narcissism [4].

The rapid development of information and communication technology (ICT) facilitates a round-the-clock interaction among adolescents. The explosive increase in online connection has shaken their growth and development bio-psycho-social-moral-behaviorly and changed the traditional socialization processes. Adolescents use online communication more often than offline means [5]. As heavy-users of ICT, adolescents enter to an ever-changing cyber-environment, which on one hand promotes opportunities and threatens established social relationships on the other. Compared to their parents when they were young, adolescents nowadays have a much wider connection with people of different background, age, ethnicity, nationality, classes, and from different places. At the same time, they share somewhat similar experiences with their parents in terms of engagement with others physically [6]. The growth of smartphone and social media not only allows people to share information but also provides a platform to induce bullying and harassment [7]. The misuse of social media causes discourses such as bullying, offensive content and hate speech [8]. It was also found that cyberbullying is associated with smartphone addiction among university students [9]. Against this background, evidence-based positive youth development (PYD) programs are designed to help prevent problems facing adolescents. The project P.A.T.H.S., which finances the design and development of these DPYD games, is one of them [10-13].

LITERATURE REVIEW

Many studies report that adolescents encounter problems with PRs. One study found that 57% of adolescents experienced different kinds of offline interpersonal victimization such as bullying or sexual abuse, while 23% of the respondents, aged 10-17 years, experienced online interpersonal victimization like sexual solicitation or harassment [14]. The same study also found that 73% of the respondents who were victimized online also reported offline victimization [14]. Besides, it is reported that adolescents who experienced online sexual solicitation were two times more likely to suffer from substance abuse or depressive symptomatology [14]. Another study found that 42% of college students experienced online interpersonal victimization [15, 16].

Positive Psychological Constructs

Twenty positive psychological constructs, also called character traits were used for providing feedback to promote PYD. They came from the book “Character strengths and virtues: A handbook and classification” by Peterson and Seligman [2]. It describes the VIA classification of character strengths and virtues, where VIA stands for ‘the way’ or ‘the path’ in Latin. It is used as a measurement tool to assess 24 character strengths which are grouped into six areas. In the three DPYD games, we have chosen 20 character traits out of 24, which are appropriate according to the contents and scenarios of the games to help students understand their character strengths and work towards improving their desirable traits while playing the games. A percentage of each positive trait is displayed to illustrate the degree of strength. The strengths of curiosity, love of learning, zest, as well as the appreciation of beauty and excellence are not measured in the games because the stories do not cover these elements. The contents of the 20 character traits are described below [17].

Group A: Transcendence (Gratitude, Hope, Humour, and Spirituality)

Group B: Temperance (Forgiveness, Humility, Prudence, and Self-regulation)

Group C: Justice (Teamwork, Fairness, and Leadership)

Group D: Humanity (Kindness, Love, and Social Intelligence)

Group E: Courage (Bravery, Perseverance, and Honesty)

Group F: Wisdom (Creativity, Judgment, and Perspective)

Definitions of the 20 Traits

The definitions of four traits with an asterisk have been amended because the main theme of these games is only about on-and-offline PRs.

A1 Gratitude*: Know how to get along with others and treat them with respect; appreciate their qualities.

A2 Hope: Be positive; work hard to achieve goals; believe that one can work towards a brighter future.

A3 Humor: Remain calm and undisturbed even when faced with adverse situations; express in an innovative and hopeful way; avoid being awkward; solve interpersonal conflicts

A4 Spirituality*: Have a positive faith in life; work hard at personal growth; and have a realistic plan to achieve goals.

B1 Forgiveness: Be willing to forgive others and give them another chance instead of getting revenge.

B2 Humility: Remain humble of achievements; does not seek attention from others.

B3 Prudence: Be very cautious, never does anything that will be regretted later.

B4 Self-regulation: Do not engage in any unlawful acts; able to think about others, and control emotions.

C1 Teamwork*: Be able to be a good friend, and candidly point out the faults of others.

C2 Fairness: Treat everyone the same way, and not let feelings affect judgment.

C3 Leadership*: Value and maintain good friendships.

D1 Kindness: Care for and get along well with others; value good relationships with others.

D2 Love: Treat others in a friendly way, willing to assist and care for others.

D3 Social Intelligence: Be able to see things from others' perspectives; able to control emotions when with others.

E1 Bravery: Will not back out when facing difficulties; able to speak out even if it might make one unpopular; act accordingly to what one believes in.

E2 Perseverance: Adopt appropriate means to deal with difficulties; persevere and take pleasure in completing tasks.

E3 Honesty: Express candidly, with no pretenses; be responsible for one's own actions and feelings.

F1 Creativity: Able to come up with new methods when dealing with others.

F2 Judgement: Able to consider things from multiple perspectives; objectively make judgments and not be affected by feelings. Change views when presented with new evidence.

F3 Perspective: Very observant; able to suggest valuable views and good advice.

A positive association is found between a person's positive psychological constructs and his/her well-being [18]. Besides, such constructs are suggested to act as one of the sources of positive emotions [18]. Moreover, a significant correlation between the positive psychological construct and the health outcome is reported [19].

Conflict Resolution Strategy

The Thomas-Kilmann Model [20] is adopted in the game design to illustrate the options we have when handling interpersonal conflicts. There are two dimensions in the model. First, the vertical axis, which includes assertive options, represents conflict responses based on our attempt to get what we want. Second, the horizontal axis shows the co-operative options and is concerned with responses based on helping others get what they want. As a result, it creates five basic types of response – competing, accommodating, avoiding, compromising, and collaborating.

First, “competing” is an assertive and un-cooperative approach to resolve conflict. For example, one is standing up for his/her rights, defending a position which one thinks is correct or simply trying to beat the opponent. Second, “accommodating” is an unassertive and co-operative approach. This might take the form of selfless generosity, giving in to another person's orders or yielding to another's point of view. Third, “avoiding” takes an unassertive and un-cooperative approach to conflict by simply not dealing with it. It might take the form of diplomatically sidestepping an issue, postponing it, or withdrawing from a threatening situation. Fourth, “compromising,” which is located at the centre of the model because of

both of its assertive and co-operating approach to a certain extent. Both sides get something but not everything. Lastly, “collaborating,” is the opposite extreme of avoiding, where both parties can come together, reach a consensus, and get what they want if they join hands. It requires developed conflict resolution skills based on mutual respect, a willingness to listen to others, and creativity in finding solutions.

Rahim’s Meta-Model of Conflict Management

Rahim and colleagues [1] pointed out that there is no single best approach when it comes to decision making or managing conflict as agreed among management scholars. Rather than having a specific model for managing conflict, Rahim created a meta-model, which focuses on the conflict styles based on two dimensions: concern for self and concern for others. There are five conflict management strategies or communication modes according to this framework. They are:

Dominating: One party primarily focuses on winning over the other party regarding the subject of concern. He/she often ignores the needs or expectations of the other party in the process.

Avoiding: One ignores and fails to acknowledge or find solutions for a concern that affects him/her and the other party.

Compromising: It involves thinking for the other party when dealing with a conflict, and both parties often give up something to reach a mutually agreed decision where give-and-take occurs in the process.

Obliging: It involves minimizing the differences while highlighting the common grounds to appeal to the other party of concern.

Integrating: It involves being open-minded, exchanging information, seeking alternatives, and studying differences when trying to resolve an issue in a manner that is acceptable to both parties.

In these three games, students face different storylines, scenarios and they have to choose a response from six choices in each scene. These choices represent five different communication styles namely aggressive, passive, submissive, passive-aggressive, and assertive. Students get feedback about their communication modes during a conflict and their personality traits at the end of the game. Instructors can make use of the opportunity to discuss these different modes and how they work in different scenarios. Students can always play the game again and try to choose a different communication style to observe the different outcomes.

GAME DESIGN

Each game has a unique story-line and provides twelve scenarios for students as the story develops. In each scenario, students are given six different responses to choose, and the choice will affect the development of the story accordingly. At the end of the game,

Third, based on the choices, the relative strengths on each of the twenty positive psychological constructs [2] in percentage format will be shown (This will be discussed in details in the next section). Even though some behaviors seem undesirable, they also have positive implications from the perspective of positive psychology. For example, fighting requires a sense of courage without rational thinking while avoidance implies self-restraint which may reduce the chance of deepening a conflict. Students pick their preferred choices in each scenario of the simulation game, where different feedback and scores on the personal traits will be given accordingly.

Figure 3. A typical feedback on the player's twenty positive psychology traits based on their use of different communication modes in the game.

Calculation of the Percentage of the Positive Psychology Constructs

There are 12 scenarios in the games as the story goes on. The player has to make a choice among six options. Two responses are from the competing mode while the other four from avoiding, accommodating, compromising, and collaborating modes. The idea of using animals to represent different communication modes was considered [21]. For example, shark for competing, turtle for avoiding, teddy bear for accommodating, fox for compromising, and owl for collaborating. Using animals as gimmicks may be attractive but it may be confusing and distorting because different cultures may attribute different meanings to animals. For example, a fox may be interpreted as cunning and dishonest and a turtle may have an insulting connotation.

In assigning weightings to different responses for players to choose, the research team first worked on the definitions of all the constructs from positive psychology. After reaching a consensus of the definitions, two team members were assigned to use a 6-point scale (5 being the highest and zero the lowest) to rate each of the response in the game according to the level of the twenty positive psychology constructs. For example, the response "You guys peek on others' private life? Why did you act so despicable?" is given zero marks for the construct of "social intelligence." In the end, each response will be given a score based on how the player responds according to the communication mode used in each scenario. After obtaining all the scores, the constructs with a huge difference of scores between the two members were

reviewed and the scores were adjusted accordingly after discussion. Finally, if there were still differences, the mean scores would be used. Table 1 shows the assigned ratings for each positive trait on each response in one scenario.

Table 1. An example of assigning weighting for each positive trait on each response

Positive Trait	Transcendence				Temperance				Justice			Humanity			Courage			Wisdom		
	A1	A2	A3	A4	B1	B2	B3	B4	C1	C2	C3	D1	D2	D3	E1	E2	E3	F1	F2	F3
Choices																				
I won't do such immoral things! (Competing)	3	3	1	3	1	1	3	3	3	3	2	1	1	2	3	0	3	2	3	3
You are so despicable, going through other's private things! (Competing)	0	2	0	1	0	0	2	2	2	2	0	0	0	0	2	0	2	0	1	1
You're going through other's private things? Why are you so despicable? (Competing)	0	2	0	1	0	0	2	2	2	2	0	0	0	0	2	0	2	0	1	1
I won't join you on such an immoral thing! (Competing)	2	3	1	3	1	1	3	3	3	3	1	1	1	1	3	0	3	2	2	2
Thanks, but I'm not that despicable, snooping through other people's private stuff. (Competing)	0	2	0	1	0	0	2	2	2	2	0	0	0	0	2	0	2	0	1	1
Silently join them. (Avoiding)	1	0	0	1	1	1	0	0	0	0	1	1	1	1	0	0	0	0	1	1
Go closer to take a look, but keep silent. (Avoiding)	1	0	0	1	1	1	0	0	0	0	1	1	1	1	0	0	0	0	1	1
Excitedly join Lilith by her side, and look at the photos together. (Accommodating)	2	1	2	1	2	2	0	0	0	0	2	2	2	2	1	1	1	1	1	1
Reply happily, "Yeah definitely!" (Accommodating)	2	1	2	1	2	2	0	0	0	0	2	2	2	2	1	1	1	1	1	1
"I don't think there's much to see on there, let's watch this crazy video online instead!" (Compromising)	2	3	2	3	3	3	3	3	3	3	3	3	3	3	3	2	3	3	3	3
"Nah, I'm not that interested in him, I didn't know you guys were, till now! Haha!" (Compromising)	3	3	3	3	3	3	3	3	3	3	3	3	3	3	3	2	3	3	3	3
His photos must be very interesting, or else you guys wouldn't be this happy. I want to join you guys, but I won't look at other's private things without their permission, isn't that right guys? Class is almost starting, let's just go back to our seats. (Collaborating)	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5

Note: Please refer to the section "definitions of the 20 traits" for the name of each trait.

The Calculation Method in the Game

The game will randomly draw two from the five competing responses and one from the two for the other four communication modes for the player. This will facilitate students to replay the game for better outcomes. A player has to make twelve choices in the game and each choice may include some or all the twenty constructs in the background. Each construct has to be calculated independently in the 12 choices to obtain a cumulative score. For example, if a player obtains the score of 1 (minimum is zero, maximum is 5) in all the 12 scenarios on the construct of “social intelligence” which is relevant in all responses, the calculation using the percentage as a representation will be: $(1 \times 12) / (12 \times 5) \times 100\% = 20\%$. The formula will be adjusted if a specific construct is not relevant in certain situations. It has to be noted that this percentage is calculated according to the choices of the player. Depending on the attitude of the player, the calculation could represent the player’s character. This statement has been included in the instruction manual.

An Illustration

The second scene of the first game is presented below for illustration. The story goes: “During recess time on Monday, Lilith and another classmate are whispering in a corner of the classroom, and there are sounds of laughter from time to time. You get curious, and approach them. You find out that they are secretly browsing another classmate’s phone, looking at the photos on it. At this time, Lilith asks you to join them, how will you react?”

Figure 4. An image captured from the screen on the second scene of the game.

Figure 5. Players are offered six randomly generated choices for the five communication modes.

TEACHING TIPS

Instructors can remind students that the percentages as shown in the personal traits are only calculated based on their choices and the percentages should be used as reference points only. For example, if the percentage of a trait is below 20%, it requires much attention and thoughtful discussion with the students; and if the percentage is 60% and above, it shows that the performance of that trait is excellent and instructors can encourage students to examine what leads to such feedback and reflect on the different responses adopted during the game. More importantly, the scores on different traits vary among students and should not be seen as a representation of students' conduct. Instead, they can only be served as a reference point to help students be aware of the availability of different choices which may affect the overall analysis of one's traits in a simulation game of BCB incidents. Having a higher or lower percentage on different traits does not imply that one is a better person or not. Instructors can clearly explain to students that although achieving a higher percentage is desirable, all traits are positive, and students can play again getting a lower score in certain traits to find what makes the difference. Moreover, instructors may stress that everyone has different personalities and predispositions. Students should be mindful of this and take the result as an opportunity to further understand themselves and reflect on which areas they would want to improve on. Instructors must strongly emphasize that points and scores should not be treated as a means of competition among students, which defeats the purpose of the games.

DISCUSSION

These DPYD games boost several PYD constructs including moral competence, resilience, and prosocial norms. According to Green and Norrish [22], school-based positive psychology interventions are programs which hope to boost students' well-being or build competence within the school context. It is proved that positive psychology is effective in raising students' holistic well-being [22].

Besides, the use of game-based learning is an effective intervention in therapeutic intervention. It is found that the therapeutic board game is proved to help patients to talk about their personal experiences, feelings in a creative way and a comfortable situation [23]. Moreover, an interactive multimedia game called *Lucity* is proved to engage adolescents and facilitate communication regarding sexual violence and other sexual health issues, and thus it proved that game-based interaction is a feasible method for students to acquire new knowledge [24]. Furthermore, Van Lippevelde et al. [25] found that a gamified app is effective to change adolescents' snack intake. It shows that the game-based intervention is an effective behavior change strategy which is attractive for youngsters [25].

There are two issues that deserve our attention. First, in design level, how the design motivates students to learn through playing the game. Second, in practice level, how teachers and human services personnel can maximize the intended learning outcomes.

The following table summarizes the game elements used.

Table 2. Illustration of game elements in the game “The digital age”

Game element	Illustration
Story	A simple matter turns out to be a complicated one because of the misuse of ICT, disrespect for others, and intrusion of privacy
Choices	Players are given 6 Choices at each decision point
Attractive	Use of cartoons and illustrations
Curiosity	The story develops with around 12 scenarios
Real life	The story is based on real-life cases
Adaptive learning	Receive individual feedback at three levels

The game elements are the major components in the application of gamification [26]. Story-telling is proved to be an essential component in gamification applications since it helps enrich barely stimulating contexts, and thus raise people’s interest [27]. There are three story forms which include linear, branching, and modular [28].

Moreover, choices are important for adolescents according to self-determination theory of motivation [29]. A research revealed that the satisfaction of autonomy is positively associated with the intrinsic motivation of respondents [26]. If the options are relevant to players’ interests and goals, manageable, and consistent with the values of the students’ culture, the motivational effect will be enlarged [30]. Since different choices of reaction in online and offline interpersonal encounters may result in different consequences, the game can send important messages which include “You have choices!” or “You can make a difference!”

Aside from it, attractiveness is a crucial game element in motivating students to learn. It is proved that the use of cartoons positively influenced constructive learning, cooperative learning and collaborative learning among students [31].

Furthermore, curiosity is one of the underlying forces for a person to learn [32]. It is found that an individual’s curiosity is positively related to his/her knowledge acquisition [33]. Thus, it is an essential game element during the application of gamification.

Besides, adaptive learning applies computer algorithms to organise the interaction with the learner. It is an educational method which uses computer algorithms to organise the interaction with the learner and deliver customized resources and learning activities to address the unique needs of each learner. A research found that adaptive and interactive digital learning enhances students’ perceived competency and their learning satisfaction [34].

Recommendations for Teaching

The games aim at arousing students’ interests and motivation to learn how to handle online and offline interpersonal relationships. First, instructors choose one of the games to give a brief introduction and demonstrate how to play the games in classes or an assembly. They could draw students’ attention to the different choices available in each scenario which will lead to different endings. The first level of feedback - ‘Reflection and Learning’, displays the result or consequences of their choices. Second, instructors could encourage students to play the games more than once. Students could play different roles such as bullies (i.e., player could choose to threaten to take revenge, edit pictures of the bullied and post it on social media, or hurt the bullies), victims (feeling helpless, keeping quiet, pretending not seeing, and

crying when bullied), or bystanders (watching silently your classmates peeking at the pictures of another classmate's phone without permission) in each scenario and observe different results. Instructors could encourage students to try putting themselves in the shoes of the victim and experience the pain while playing that role. Discussion among students relating to that aspect can arouse more empathy when students are sharing the experiences and their feelings with each other. Besides, students should be encouraged to discuss the strategies to resolve on-and-offline interpersonal conflicts according to the second level feedback, which is an analysis of communication mode according to students' responses in the game with five categories: dominating, integrating, compromising, avoiding, and obliging. Explanations of each term will be given; what the player is like in communicating with others in terms of attitudes, actions taken, and thought processes will be displayed as a percentage under each category. Third, instructors could encourage students to examine and reflect on the contents of the third level feedback, which is 'Character Trait' and set goals to get higher scores on specific desirable positive traits by adjusting their choices in the game. The game makes use of twenty character traits and is presented in the form of percentages. Explanation of each trait is given so that students can understand the meaning of each trait and reflect on their own traits accordingly using the percentage as a reference. Relative strengths on each of the constructs in percentage format based on the choices of students will be shown. It is hoped that students can experience compassion or even empathy in the simulated game settings if they treat the materials as a learning tool rather than merely a game.

The Roles of Instructors, Social Workers, and Students

Instructors play the roles of teaching and facilitating in the learning process. They need to familiarise themselves with the content of the game materials and the relevant teaching units for the particular class (Grade 7 to Grade 9) to fully utilise the teaching materials and achieve the purpose of the game. This will be further elaborated in the individual game section in later sections. Instructors need to be aware of the technical aspects involved in the operation of the games and thus, provide support to students if they come up with issues relating to those aspects. Therefore, instructors need to know how to use basic ICT tools and media to guide students through the teaching materials. They could explain the teaching and learning methods and strategies with the whole class, demonstrate part of the games, and allow students to use the teaching materials on their own after class.

The role of the instructor includes not only planning the lessons, but also facilitating learning and discussion in class, answering students' questions, and managing the class time to fully utilize the lesson to achieve the goals of each class. When time is a concern, instructors can encourage students to participate and work on the games on their own so that they can have their feedback and questions ready for discussion in school. Also, those topics and scenarios which are of more interests to students can be allocated more time for students to express their areas of concerns and opinions for further discussion in class i.e., cyberbullying. Instructors can have students discuss the game in groups, and pay attention to any concerns and disagreement they have in responding to certain scenarios. Thus, they can then facilitate discussion and provide guidance for students to engage their thinking processes from different perspectives.

Social workers and counsellors can use the game materials when working with students who have been facing those issues in their daily lives. Of course, there is no way we can look at students' responses in the scenarios due to confidentiality and the software design. However, social workers can invite students to play the games and discuss with them about their responses, and issues they are facing in their lives regarding bullying for example. Students can be encouraged to compare different outcomes of the ending in the game by choosing different responses. It can be done by saving the feedback of each stage in the game using the saving screen function or printing out the page of feedback. Also, counsellors can make use of the teaching materials for individual or group counselling.

Students have a high degree of autonomy in the learning process. They should take full responsibilities of their learning by playing the games in their spare time after school, deciding on what aspects they want to learn and which areas they want to improve, as well as engage in meaningful discussion with their peers on issues raised in the games. The goal is to achieve peer learning; students understand each other's different responses in certain scenarios in the games, and be ready to engage in meaningful and purposeful conversations of the topics.

All these three games are targeting the constructs of moral competence, social competence, and resilience. Apart from some universal points shared by the three games categorised under theme 1, each game has its unique characteristics, story-lines, and objectives to achieve. They will be displayed in the following sections one by one to help schools and organisations make better use of each game on its own.

Teaching Points

Some adolescents use cyberbullying to humiliate, threaten and harass others. In the process, it always causes harm to the victims psychologically and mentally in their daily life [35]. Instructors could discuss with students how to distinguish right from wrong when faced with cyberbullying incidents. There is always the option of reporting the incident to teachers or social workers. More importantly, students should be reminded to stay firm and refuse to participate in any cyberbullying activities.

Instructors could encourage students not to publish anything that is not in accordance with facts to avoid hurting others; do not be an instigator; never gather others to participate in cyberbullying; advise others who participate in cyberbullying to stop their bullying behaviors; do not take revenge for others who are being bullied, but immediately seek help from teachers and social workers; and maintain an objective and neutral attitude in handling information on the internet.

The games arouse students' attention to properly handle BCB which are common phenomena on and off campus. Most students have experienced being one of those roles as the bully, the victim or the bystander, and it is not difficult to recall what those scenes are like and how they felt. Instructors are in a good position to bring out the importance of choice, and how different responses may lead to a more desirable and fairer outcome to all parties. It does not help by avoiding, arguing, or fighting with the bully, and students need to take actions such as seeking help from social workers or discipline masters when a bullying incident occurs.

CONCLUSION

To summarize, this set of three games has four major contributions. First, they provide knowledge and skills for adolescents in handling peer pressure properly. Second, they offer choices so that players can learn vicariously and use the trial-and-error strategy in a simulation game. As there are male and female versions, the principle of gender-sensitivity has been observed. This will also attract adolescents to try the two versions for better learning outcomes. Third, they create chances of cooperative learning that encourages support and open discussion rather than didactical communication and competition. The game design maximizes the positive effects of the reciprocal relationship among peers. Fourth, they demonstrate how to use game elements to design DPYD games in preventing fragile PRs from turning into BCB incidents. By helping adolescents review their communication modes and positive traits critically and substantially, it helps promote PRs.

ACKNOWLEDGMENTS

The design and production of the 7 digital PYD games introduced in this special issue, the preparation of this work, and the Project P.A.T.H.S. were financially supported by *The Hong Kong Jockey Club Charities Trust*. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

This chapter presents a brief literature review on the issue of intrusion of privacy among adolescents followed by a description of the project P.A.T.H.S. which sponsored the design and production of a digital positive youth development (DPYD) game to strength moral competence, social competence, and pro-social norms among early adolescents. It then describes how it can be used to promote respect of privacy in the use of information and communication technology (ICT) as an important component of media literacy. A detailed description on how to make the best use of the game together with the use of related teaching units of the project P.A.T.H.S. for primary prevention is given. To demonstrate the potential impact, a male and a female young users from China and the United States were invited to play and comment on the game design and give feedback in terms of perceived effectiveness. A discussion of how to use the game for secondary prevention is also presented.

INTRODUCTION

Early adolescents have entered the digital age since early childhood. Their experiences of interaction and connection with others have been transformed by the frequent use of information and communication technology (ICT). The face-to-face physical contact meet one another has reduced drastically to texting or video calling due to the advancement and availability of ICT. This phenomenon is particularly evident in our youth population, not only locally but globally as well. The number of social media platforms and messaging applications is rising at an alarming rate considering the high number of young people using those platforms. Online social groups have become a part of their identity. The inadequate media literacy for children and early adolescents is one of the major concerns for both parents and educators. Teens are easily attracted by the new technology and the search for identity and belonging in their peer groups. It could put them at risk of disclosing their personal information to others and even strangers, who might have bad intentions. Information such as their names, age, gender, home address, school attended, as well as pictures of themselves and family and friends they posed could be obtained by others if they are not careful in the process of sharing information. The consequences can be severe – misuse of personal data, stolen identity, financial loss, harassment, or victims of sexual crime.

This chapter first outlines the change of mode of communication and interaction, and we can easily connect to someone thousands of miles away with a click on the phone. It is exceptionally true for our adolescents, who spend a great deal of their time on social media on a daily basis. The literature on the issues of privacy invasion revealed insufficient awareness of privacy protection as well as media literacy. The research team has, therefore, designed the game, ‘The digital age’, to bridge the gap of this inadequacy. The pilot of the game was locally and elsewhere welcoming. Positive feedback and constructive recommendations were received to help improve the game features. It is hoped that more PYD games will be used to educate students on the importance of this matter and prevent the intrusion of privacy and misuse of personal data.

LITERATURE REVIEW

The means of communication and maintaining friendship has changed drastically over the past fifteen years to devices with internet connectivity. We are now able to interact with millions of people with different backgrounds all over the world and receive instant information behind the screens. However, it also decreased the quality of interaction that led some of us completely incapable of carrying out a normal and meaningful conversation or interacting with other people in person. It is because of the growing inability to read social cues and body language, as well as the increased dependency of using more simplified written language. The increased use of social media and messaging service in recent years has also taken us to the hidden risk that can endanger our personal safety and well-being – privacy concerns. People are getting more used to meeting new friends and sharing their everyday activities through social media networks. They may also upload their sensitive information to their personal profile, which is often required for online service usage, with the massive data and messages stored online in the cloud of the social media network and messaging

companies. Choi, Park and Jung [1] conceptualized a phenomenon called privacy fatigue, a sense of weariness toward privacy issue for users who believe that there is no effective means of managing their personal information on the internet. In 2014, 500 million Yahoo user accounts were compromised with an involvement of more than 1 billion users [2]. The unguarded practice of diminishing the potential risk to information privacy can lead to the violation of privacy boundaries or privacy security breach by our friends and anyone on the internet.

The influx of social media networks and messaging services have been fully embraced by adolescents for their own social purposes and the exploration of their identity. In a report published by Common Sense Media, the percentage of adolescents checking their social media networks for more than once a day has increased from 34% in 2012 to 70% in 2018 [3]. With more than 81% of adolescents aged 13 to 17 reported that social media makes them feel more connected to what is going on in their friends' lives, they often associate their social media use with positive rather than negative emotions [4]. This age group is particularly linked with a higher risk of exposing their personal and sensitive information due to the insufficient awareness of the management of privacy. For example, there was a television interview of a female student concerning about revealing personal information on Facebook reported by Barnes [5]. When the student was asked to show her personal Facebook page, it contained all the information about her home address and phone numbers. It is clear that she already revealed too much personal information, whether or not she was attentive to her level of privacy protection of the social media networks. However, in a study that examines the tendency of adolescents sharing their personal information on social media networks in public or private profiles, females were 1.5 times more likely than males to have their profile set to private, while age did not indicate any significant difference. The decision in keeping their information public or private can bring negative impact to students as schools, college officers, and future employers are reportedly checking these social media networks to learn more about the potential background of future students and employees. Personal and sensitive information and pictures revealed online can negatively impact the perception of students.

The frequent use of online media platforms can also lead to other psychological issues that have been widely discussed in recent years. "Fear of missing out" (FoMO) originates from social psychological deficits in people's competence and relatedness needs. It is a pervasive apprehension that others might be having rewarding experiences from which one is absent, and characterized by one's desire to stay continually connected with what others are doing [6]. It was found that adolescents with a high level of FoMO used Facebook more intensely and had the feeling of stress when not connected on Facebook [7]. The frequent presence on Facebook and FoMO was related to problematic Facebook use severity [8].

Tension and conflicts among friends may happen on many occasions involving the misuse of ICT. When adolescents found that they were not being invited to activities or events by their close friends, they are likely to experience some hard times, and perhaps, believed that they are being left out on purpose. Sometimes fabricated information, pictures, or even videos of someone would be sent to different groups in social media networks without the awareness and consent of the person involved. Furthermore, they may get bullied for revealing their personal information online and being teased for an act that was supposed to be personal and private. The inconsistency with the common norms in school or social circles can lead to social bullying. It appears to be a matter of weighing of perceived benefits between committing to online social networking and risks of disclosing personal information

[9]. The common strategy of safeguarding personal and sensitive information in private is to decrease profile visibility by restricting limited access to friends only and block access to strangers [9, 10]. Improving their awareness of the underlying risk of mismanaging their privacy protection is a good strategy to warn students of its potential harm. It could lead to the misuse of personal data and harassment by other parties.

The need for protection and respect of privacy is an important issue for all, especially for children and teens. It is an important part of media literacy which is considered as one of the 21st century skills. For this purpose, a digital positive youth development (DPYD) game was developed.

GAME DESCRIPTION

This is the first game of a series of three closely related games that share the same theme of on-and-off-line interpersonal relationships. They are designed to support the P.A.T.H.S. project as electronic teaching and learning resources.

The P.A.T.H.S. to Adulthood

Sponsored by the Hong Kong Jockey Club Charities Trust and co-organized by the Social Welfare Department, the Education Bureau, and a research team comprising academics from five universities in Hong Kong, the “P.A.T.H.S. to Adulthood: A Jockey Club Youth Enhancement Scheme” project was initiated in 2004 to provide primary and secondary prevention through enhancing of positive youth development constructs. The project was a curricula-based intervention program focusing on fostering adolescents’ psychosocial competencies, developmental assets, healthy relationships, and their well-being. Throughout the program, holistic development is promoted among adolescents to better prepare them to meet various challenges in their paths to adulthood. Up to 2018, more than 284,400 students in 320 secondary schools have participated in the project. More than 7,000 teachers and social workers have benefitted from the training.

Research showed that the program was efficacious in addressing peer and individual risk during adolescence [11]. Supported by evidence, positive feedback has been received since the launching of the P.A.T.H.S. Participating schools appreciated that the program’s invaluable experience brought meaningful and positive changes to the development of youths [12]. It is clear that the reference materials of the project would continue to give precious contributions to the education and social welfare sectors incessantly. The project was recognized by the World Health Organization as an evidence-based program in one of the seven strategies for ending violence against children [13] and one of the three evidence-based programs for promoting life and social skills in adolescents [14].

Game Story

Players are given an incident of disrespect of personal privacy by a classmate on a social media platform. They have to choose a response out of six different options as the storyline

develops. Feedbacks on three levels are provided to the player at the end of the game for self-reflection and evaluation.

Targeted Participants: S3 Students

The related teaching units and constructs of the game (will be elaborated later in this section) especially the foundation and knowledge of the issues of the modern digital age can start at S1 (Grade 7). It is essential to instil the concepts and the content gradually so that students can further build their knowledge on previous learning when they advance through the junior high school years. Using selected teaching units on targeted participants serve the purpose of preventive education. For this game 'The digital age', a teaching unit of 'Lying or Not' is designed for S1 (Grade 7) students. Two other units, 'Unresolved' and 'A blog post a day' are designed for S3 (Grade 9) students. It not only consolidates the information they received previously but also introduces related subject matters under the same theme to help students see the bigger picture of the complexity of the digital age. The time needed for demonstrating the game is about 10 to 15 minutes.

Game Contents

The game highlights the issues created through the misuse of technology and the invasion of privacy, which is a common phenomenon in today's world. It examines the importance of honesty in the context of cyberbullying. Advanced technology allows us to take and share photos or messages with others through social media instantly. However, as efficient and convenient as it is, misuse of information and communication technology (ICT) could easily lead to abuse, dishonest and criminal behaviors, such as infringement of rights, social media fraud, bullying, online dating traps and technology crimes related to online games. Therefore, honesty is a very important principle in this game. Instructors should this point out. Students can pick either the male or female version in the game.

Figure 1. An image captured from the screen of the game.

Objectives of the Game

There are various objectives of the game. First, on the cognitive aspect, it aims at helping students understand the boundary of privacy, the need to deal with privacy issues in an honest and careful manner, the need to respect the privacy of others, and that there are different ways to tackle bullying. Second, on the emotional aspect, students can change from understanding the victim's plight to caring for the victim (sympathy), and to showing compassion (empathy) for the victim's pain and negative emotions. Third, on the behavioral aspect, students can consciously practice honest behaviors, take appropriate actions to deal with interpersonal conflicts, reduce the behaviors of escalating bullying incidents, and prevent the worsening of those incidents. Instructors should encourage students to use the game repeatedly and observe the results generated from different responses. In this way, it stimulates their thinking processes and makes them aware that they have choices, and it will lead to a different outcome accordingly. That is when learning a new way of response or changing a behavior starts to emerge.

Game Design

Based on a campus story, students play the role as the main character, who has to handle interpersonal conflicts when his/her privacy is invaded by classmates. The story consists of different scenarios and develops differently according to the responses of the player. Players have six responses to choose from in each scene.

The first level feedback is based on students' choices during the early stage of the story when a classmate sneaks a peek at another student's mobile phone and the ending (the tenth episode of facing the bullying). The second level feedback presents the player's pattern of handling interpersonal conflicts. The third level feedback presents the calculated scores of the twenty positive psychological constructs that reflect the choices of the students.

For detailed description of the game design, please refer to chapter 3.

Game's Storyline

Regarding the learning process, students are given a situation where he/she is bullied by a classmate on a social media platform at the beginning of the game. Rocky and Lilith (the male/female main characters) are very popular in class but often abuse the use of ICT and invade others' privacy. As a player, students are tempted to join them and have to make a difficult choice on whether to maintain their friendship with the bullies or stick with their integrity and honesty. Students are given six different responses to choose from in various scenarios as the story continues, such as peeking on other's phone and social media site, posting other's photo with no permission, and bullying and teasing friends on a group chat. Different scenarios and options are presented for students to choose, and the story develops according to the choices they make. In other words, their choices directly affect the outcome and the ending of the story. For feedback, the first level feedback will be given according to an early stage of the story when a classmate sneaks a peek at another student's mobile phone.

The ending is around the tenth episode when students face the bullying incident directly. The second and third level feedback will be provided at the end of the game on the players' pattern of handling interpersonal conflicts and their personal traits.

Tips for Instructors

Instructor needs to familiarize himself/herself with the storyline, the teaching points, and the plot of the game. They can remind students to pay special attention to the issues surrounding violating others' privacy and disrespecting others throughout the game. There are plenty of places in the game where instructors can pause the game/game demonstration to dig deeper about the issues with the students in the form of class or small group discussion if time allows. For example, the instructor may inspire discussion about making difficult choices between maintaining a relationship and being honest in Scenario 2 (when the player was asked to join Luke/Lucy to browse through the photos of another classmate's phone without consent). Questions that can be used to generate discussion throughout the game include: As a friend, would you dissuade your friend from the dishonest behavior? If your friend tried to dissuade you from dishonest behavior, would you stop the behavior and admit to your faults? Did your final decision effectively protect your personal rights to privacy as well as resolve conflicts with others? If not, how could you improve the situation?

PYD Constructs and Related Teaching Units of the Game

This game is suitable for use together with one or more of the three units listed in Table 1. The PYD constructs behind are moral competence (MC), resilience (RE), and social competence (SC), prosocial involvement (PI) and prosocial norm (PN). Table 1 summarizes the constructs and their related teaching units in various classes.

Table 1. PYD constructs and the names of the related teaching units

Game	Adolescent Issue	PYD Construct	Curriculum Unit Code and Name	Grade
Digital Age	Disrespect of privacy; Inappropriate use of ICT	Moral Competence (MC)	MC1.2 / IT1.1 'Lying or Not'	7
		Resilience (RE)	RE3.3 / IT3.1 'Unresolved'	9
		Social Competence (SC)	SC3.4 'A Blog Post a Day'	9

The curriculum of the P.A.T.H.S. Project has been revamped twice since 2009. The constructs and their illustrations in different teaching units are displayed in a set of concept maps. A total of 289 concept maps for all the teaching units and constructs can be found at <http://www.cityu.edu.hk/ss/pltr/ty/new/en/enter.html>. After the second revamping, five themes of adolescent issues were developed. They are Anti-bullying Education (AB), Anti-Drug Education (AD), Internet Use Education (IT), Money and Success Education (MS), and Sex Education (SX). All the teaching materials in the revamped teaching units can be accessed on the P.A.T.H.S. website (<https://www.P.A.T.H.S..hk/en/>).

In this section, the construct of moral competence, resilience, and social competence are displayed with different sets of concept maps to further explain how the concept works in relation to the theme and scenarios in the games.

Construct: Moral Competence

Figure 2. The concept map of Unit MC 1.2 (IT 1.1) ‘Lying or not’.

Teaching Points

Living in the era of technology, individuals can easily use the internet in a reciprocal manner. At the same time, issues of honesty when surfing the net arises. It is of dire importance for individuals to understand that lying on the internet is an irresponsible and disrespectful behavior. If it is not handled carefully, it may even harm the privacy of others and lead to the commitment of illegal behaviors. Knowing such adverse consequences, preventive measures should be taken so that individuals will learn to respect privacy.

Instructors should encourage individuals to check the accuracy of online information with teachers and knowledgeable friends. To further protect personal information, individuals should protect important personal information by using passwords, carefully verify the identity of ‘friends’ before granting them access to personal information and frequently check

their personal computers for viruses and Trojans. Finally, we ought to develop a positive mindset for individuals when using the internet. This includes having a non-greedy attitude and an empathetic mindset when posting criticisms. Individuals must carefully and cautiously consider the feelings of those being criticized before posting the criticism online, which is preferred to be constructive. Lastly, instructors should remind individuals that they are fully responsible for their own words on the internet.

Construct: Resilience

Figure 3. The concept map of teaching Unit RE3.3 (IT3.1) 'Unresolved'.

Teaching Points

The appropriate use of self is an important element when tackling issues of ICT. Individuals should not purely rely on surfing the net to get rid of all troubles. Instead, they are advised to use adaptive ways to solve problems, such as doing exercises and taking a rest. The problem solving ability could be enhanced by making use of individuals' social circles. In face of a problem, they are encouraged to seek help from teachers and good friends. Through interacting with them, individuals will gain insights, thus gradually learn to solve and positively face their troubles. Instructors should motivate students to distinguish the characteristics and usage of different resources on the internet and make good use of them to solve problems. Students should be optimistic in tackling their problems and treat them as a learning opportunity.

Construct: Social Competence

Figure 4. The concept map of teaching Unit SC3.4 'A Blog Post a Day'.

Teaching Points

Because of individual differences in principles of life, characters, traits and interests, and moral standards, there are conflicts in our inter-personal relationships with others. In the above teaching unit, students are guided by the instructor in class to discuss how to face and handle those conflicts and more importantly, to prevent intrusion of privacy. Students are reminded to maintain an honest relationship with their friends. When conflicts occur, students should never compromise their integrity and personal private information for fear of affecting the relationship. Through practising with the guidance of an instructor, it is hoped that students can learn to distinguish good friends from bad friends, and choose the appropriate action to protect one's privacy as well as others.

USER FEEDBACK – PERSONAL REFLECTION

After playing the game, a Chinese girl aged 15 studying in an international school in Shanghai wrote the following reflection. Parental consent to play the game and publish her views were obtained.

"I think that what I learned from this game is that there are multiple ways to deal with social problems regarding cyberbullying or in-person bullying, and most of them are not always 100% good or bad. Before playing this game, I thought that I would be able to make a clear distinction between what would be the most 'perfect' solution, but throughout the game, I had to really consider the pros and cons of all the answer choices because many of them seemed to be good solutions initially. Another thing I learned was that even if you pick what seems like the better solution in your eyes, it may not work immediately. In this case, you can reevaluate whether or not the solution is effective, then change it or use it again. In my case, I clicked on several solutions that had the same kind of 'attitude' in the answer, and that eventually led to the conflict being resolved." (Case No: 25)

The following is written by a male young adult aged 19 studying at college in the United States.

"I think the takeaway that I got from this game is that bullying can happen both in real life interactions and in digital environments. However, my first impression was that the game was on just bullying. However, I realize this might be a result of the environment that I have grown up in and technology is an integral part of my life. The intended audience probably has even more exposure to tech than me. Therefore, an improvement would be to emphasize that knowing how to interact online and in person are very different skills. The game should explicitly state the direct consequences and responses of the characters as a result of the player's individual choices. Maybe state at the end that there are different social norms in these environments." (Case No.: 27).

DISCUSSION

Adopting PYD games in the school curriculum has been proven effective and constructive according to our findings. Issues such as invasion of privacy and cyberbullying have been the subject of research interests for a long time. Literature has documented those issues and interventions in different parts of the world. As internet usage is on the rise in our youth population, so does the chances of potential risks they expose to daily. The consequences can be grave if they are not educated on those risks. The attributes of the PYD approach and the characteristics of the prevention science approach are compatible and could supplement each other [15].

DPYD games could be included in primary prevention programs to tackle issues that students, parents, and educators have been facing, such as respect of privacy and proper use of ICT. DPYD games in the Asian context have been limited as Shek and Yu [16] found only 14 programs out of 63 targeted the Asian youth population. Project P.A.T.H.S. has been leading the progress in continuing to develop games that serve as primary prevention to cater to both the local and international needs. Users have commented positively about the game, 'The Digital Age' and its benefits to them. Scenarios in the game provide a safe place for students to try out different responses to a potential situation they could face in real life circumstances. They receive different feedback according to their choices of response, and instructors and students are encouraged to discuss the outcomes of various choices, such as the pros and cons of them.

The pairing up of positive youth development constructs and their related teaching units give instructors further support in terms of resources and materials to consolidate the lessons learned in the game according to the students' levels (S1, S2 or S3). For example, different constructs of the game, such as resilience, social competence, and moral competence can be grouped under the subject of anti-bullying and internet use at a different level. The illustration

of concept maps makes those relationship visual and easy to comprehend, and thus, facilitates the teaching of those inter-related constructs at the cognitive level. The call for actions in each teaching unit serves as a conclusion for students to ponder on ways that they can practice what they have learned in the unit and the game to prevent intrusion of privacy.

CONCLUSION

This chapter demonstrates how school instructors can utilize the game to promote the respect of privacy and introduce media literacy in secondary school classrooms (Grade 7 – Grade 9). User feedback was received and analyzed for evaluating the outcomes of the game. A brief introduction of the topic, a description of the game, and its relationship to the P.A.T.H.S. project (Hong Kong) were laid out in this chapter. Users' qualitative comments were included, followed by a discussion on how to best adopt the game for secondary prevention. This chapter shares the process of designing and adopting a game, derived from theories, with the academic world to denote the effectiveness of gamification in the curriculum.

ACKNOWLEDGMENTS

The design and production of the 7 digital games introduced in this book, the preparation of this work, and the Project P.A.T.H.S. were financially supported by The Hong Kong Jockey Club Charities Trust. Readers may request free copies for non-commercial purposes of these games by contacting Dr. TY Lee at ty.lee@cityu.edu.hk or ty.lee@friends.cityu.edu.hk after July 1, 2020. This chapter is based with permission on a paper adapted from a special issue published in the *International Journal on Disability and Human Development* 2019;18(4) issue.

ABSTRACT

Early adolescents are often influenced by their peers to engage in risky behaviors which include deceptive behavior in families and schools. Lying has been studied for centuries and is usually seen not a serious problem unless it becomes habitual, compulsive, remorseless, or when it is complicated by the co-occurrence of other risky behaviors such as skipping school or forgery. From the preventive perspective, we can strengthen adolescents' moral and social competences through game-based learning (GBL) and positive youth development (PYD). A digital PYD game is designed to attract and engage adolescents in examining and experimenting consequences of deceptive behavior in a non-threatening and manner. It aims at promoting moral decision making through simulations and extensive feedback. It is available for free use as an electronic

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

teaching and learning resource. This chapter reviews relevant literature, followed by a brief description on the game design, and its relationship to the Project P.A.T.H.S. which is recognized as an evidence-based prevention program by the World Health Organization [1]. Two respondents from different gender, age, education, and cultural backgrounds were invited to play the game and give comments on their experiences. Based on the users' feedback and the literature, a discussion on how to make the best use of the game together with the related curriculum units for primary and secondary prevention is presented.

INTRODUCTION

Lying is common misbehavior for students. Most parents think that their children lie to get or avoid something they want or do not want to do. Children may develop an unfavorable mindset and attitude when telling lies becomes habitual through reinforcement and observations of the consequences of lying [2, 3]. In schools, students sometimes tell lies to their teachers and school prefects [4, 5]. The issue is getting more serious in the digital era [6]. According to a survey in 2009 [7], lying about being ill to skip school or work is one of the ten most common forms of misbehavior of youths in Hong Kong. Lying behavior becomes a major concern when it is accompanied with other risky behaviors such as skipping school or forgery. In a digital world when most adolescents are connected through digital means, the issue of lying will easily become complicated as the problem may magnify as it goes on-line. The issue may even lead to bullying and cyberbullying (BCB) because skipping school and forgery are considered as major deviant behaviors and could become excuses for blackmail. Importantly, however, making use of the very same social learning process to reinforce normative and prosocial behavior among early adolescents should be promoted. Against this background, a digital positive youth development game is designed and developed.

LITERATURE REVIEW

Lying refers to a person making a false statement with the intention to deceive others [8, 9]. When toddlers (ages 2 to 3) engage in pretend play, they start to develop the ability to make factually untrue statements [10]. As children grow older (3-8 years), making a false statement involves executive functioning and conceptual moral understanding abilities. Recent theory-of-mind research postulates that there are first- and second-order belief understandings [11]. The initial false denials of a child are associated with his/her inhibitory control and the first-order belief understanding, while the maintenance of false statements is associated with his/her second-order belief understanding [12]. On top of executive functioning, conceptual moral understanding and theory-of-mind understanding, other social and cognitive correlates of young children's lying behavior include age, intellectual and language abilities, parenting and disciplinary styles, as well as cultural contexts [3, 13-15].

During middle childhood (ages 9-12 years), children tend to lie more than those in early childhood [16]. Since the lying behaviors are more cognitively demanding than telling the truth, the lie error rate for children declined with age [16].

Adolescents have the highest lying frequency among all age groups [16]. The sophistication of lies is closely associated with adolescents' executive functioning skills [17]. Deception is moderately correlated with parenting styles, parent-child relationship, and behavioral and emotional problems of adolescents [5, 18]. Early adolescents usually lie to their parents but seldom to their friends [5]. According to Cumsille and colleagues [19], parental warmth is negatively correlated with adolescents' lying. It was found that a better parent-adolescent relationship is associated with less lying as youths with close relationships with their parents will have less need to lie [20]. Moreover, poor relationships with parents may reinforce adolescents to involve with peers who tend to engage in deviant behaviors and increase the propensity to tell lies [21].

Peer Cluster Theory

Numerous studies have identified contributions of friendship to a child's social, moral, emotional and cognitive development through perspective-taking, cognitive flexibility, conformity to desirable social norms, resistance to peer group pressure, making close friends, as well as learning through vicarious experiences and verbal persuasion. The processes of peer influence and peer pressure are not easy to delineate and more often confusing and ambiguous [22]. Many youth work experts suggested studying peer pressure and peer influence by peer cluster theory [23]. The theory examines the interactive process that affects youth decision making, conformity to norms, and acquisition of deviant values. When a teenager is asked by a friend to do some inappropriate things, he or she may conform in order to maintain the friendship and thereby making mistakes together. Therefore, the conflict between maintaining friendship and integrity is worthy of reflection and learning. Peer pressure happens when an individual or a peer group encourages others to change their values, attitudes, or behaviors in order to conform to those of the influencing individual or group. Peer pressure may become a sufficient condition for the onset of bullying behavior if an individual refuses to follow.

Integrity

In order to obtain the acceptance by peers and to maintain a social position within the peer group, adolescents are often influenced by their peers to engage in behaviors that were reinforced to conform to the expectation of a social group [24]. When adolescents were asked to do inappropriate things that contradict with their personal values and beliefs, the decisions and adjustment of following their moral integrity are vital in maintaining their interpersonal relationships, and as a result of self-awareness in response to the circumstances. Taking responsibility and maintaining honesty to oneself allows the person to understand and view the full picture of the situation that untangle the misunderstanding and promote strong moral principles.

From a positive view, usually, adolescents can differentiate socially desirable and undesirable behaviors. In a study, some vignettes showing internalizing and externalizing behavior problems were shown to adolescents for them to rate. It was found that adolescents

could recognize the behavior problems of vignette characters and they are likely to approach and like those who did not reveal any problem than those who showed externalized behavior problems. [25].

From Isolation to Victimization

To be independent honest to oneself requires lots of competencies and support. Being isolated is an important risk factor for being bullied. Despite the fact that all bullies were disliked, social status and feelings of rejection and humiliation are strongly related to aggressive behavior, suggesting an adolescent's social status may affect his/her tendency in doing aggressive and bullying perpetration behavior [26-28]. Bullying perpetration is constant aggressive behavior towards a person or a group of people. Olweus [29] defined bullying perpetration as, 1) repetition – it occurs repeatedly, and 2) a power imbalance happened so that the victim cannot protect him/herself. Stein, Dukes, and Warren [30] later added a criterion, 3) negative or malicious behavior intended to harm or distress. For adolescents who are bullies, Salmivalli [31] revealed a dominance hypothesis for the occurrence of bullying, in which they are driven by a desire for dominant status in the peer group. The leader can feel rewarded when their followers and reinforcers support their actions, especially when the majority of bystanders remain in a passive state. A similar pattern of the reaction was observed among children in Canadian playgrounds [32]. The prevalence of misbehavior was elevated among adolescents who reported one negative life event and more markedly elevated for those reported more than one negative event [33]. Another reason that can be attributed to taking the side of bullies is concerns of peer rejection, which is known to peak during the adolescent years [34]. For victims of bullying, research has found that the youth of ethnic minority backgrounds were more likely to get picked up due to the fact that they didn't have any distinct group to join, and for the same reason, they seldom have a group for their identity [30]. Both bullies and victims scored lower on subjective well-being than those not involved in any bullying perpetration events [35]. They are also positively related to internalizing problems across culture and time [36].

When facing risks and threats from social circles, support from family members often plays a critical role in protecting adolescents from bullying experiences. Family relationships were found to be mediated through adolescents' susceptibility to peer pressure, including school misbehavior [37]. Parental support and warmth showed significant negative associations with adolescents' misbehavior, which suggested adolescent attachment to parents is able to influence children's behavior when parents are physically absent [33]. The overall misbehavior was also four times less prevalent among adolescents in the quartile of reporting most teacher support compared to the quartile reporting least teacher support. Talking to friends for quality communication and perceived peer support were also negatively correlated with bullying perpetration or bullying victimization experiences [36], particularly for adolescent girls that are more likely than boys to turn to peers for support.

From a study that focused on coping strategies to bullying experiences, the five most frequently used strategies were to confide in somebody, ignore the behaviors, to support yourself, to get away from the bullies, and build up your social circles [38]. Some non-assertive strategies, such as crying, were commonly less efficient in tackling the issue than

actively seeking help behaviors. The most frequent solution suggested was seeking support from the school, and it is often recommended in schools [39].

For prevention and intervention strategies, it is important to understand that even research findings have shown social support from teachers, parents, and peers have negative relationships with adolescents' misbehavior at school, there is always limitations and capacity for each side to support and respond proactively. Each party should bear equal responsibility in bringing quality communication and interdisciplinary networking to support adolescents in responding to crises and implanting appropriate reactions to threats that bought by their social circles.

Positive Youth Development

Adolescents may find that some peer expectations conflict with their personal needs and values. However, in order not to lose their friends in a rather favorable cluster, they may feel uneasy to refuse which is a very important life skill of social competence. They may conform to inappropriate acts and even join risky behaviors. To resist peer pressure, adolescents need to be equipped with positive youth development (PYD) constructs [40] which include social, emotional, moral, cognitive, and behavioral competencies, clear and positive identity, self-determination, self-efficacy, beliefs in the future, bonding, resilience, spirituality, prosocial norms, and pros-social involvement. These 14 PYD constructs, together with recognition for positive behavior, are recognized as crucial constructs for any PYD programs.

Friendship

Friendship is an important part of the social and emotional developmental stage for adolescents during the period of transition between childhood and adulthood. A perceived higher level of friendship quality can bring adolescents to have a higher level of self-worth and social competence [41]. Patterson, Bettini, and Nussbaum [42] identified nine definitional clusters of friendship conceptualization across the life-span, including devotion, commonality, reciprocity, relational stratification, frequent contact, positive attributions, positive impact, understanding, and familial comparison. Friendships allow adolescents to gain social support, learn to get along with others, acquire knowledge and self-esteem, and strengthen social competence [43]. In adolescence, agreeableness, which is characterized by traits as cooperative, friendly, considerate, and helpful, is associated with better interpersonal adjustment and more harmonious conflict resolution.

Promotion of Bonding

There are many ways to build up bonding with good friends at school. They include the promotion of physical and psychological safety, the establishment of appropriate structure that promotes bonding, cultivation of supportive and intimate relationships, creating

opportunities to belong, promotion of positive social norms, support for efficacy, and provision of opportunities for skill-building [44].

The Structural Cognitive Theories of Morality

The structural cognitive theories of morality denoted the process of how individuals reason and judge their own behaviors when faced with moral dilemma issues during their active participation in engaging activities. Following the tradition of structural-developmental theorists [e.g., 45-48], Bredemeier and Shields [49] posited the example of sportspersons were actively interpreting their morality by interacting with others and making judgments on appropriate behaviors. Moral constructs, reasoning, and judgments became some of the important learning in sports participation and the same as in many engaging interactive games.

Another important concept “Ethos” [50] denotes the nature and characteristic of every unique participation that may govern the behavioral and cognitive aspects of all participants differently. Friendship, acceptance by peers and risks facing among peers are some of the vivid examples that will generate different ethos for adolescents to construe with when their integrity, honesty, and moral reasoning are being challenged. These processes of active construing the meaning of their own unique physical and mental participation echo the way for an agentic understanding [51] of the social cognitive theory of morality. The following examples illustrate adolescents are not passive recipients of their situations; they are actively interpreting how to exercise their moral will and desire. The dilemmas of making fair decisions, maintaining honesty, and upholding integrity will engender consequences, be it intentional or accidental.

Digital Game-Based Learning (DGBL)

Prensky [52] observed that people respond more effectively to fun, speed, and graphics and wrote the first book of digital game-based learning. He defined digital game-based learning as the combination of serious learning with fast-paced video-games that provides interactive entertainment. Since then, there is a growing interest in the use of digital game-based learning (DGBL) [53] in formal education [54], socio-emotional learning (SEL), mental health [55], and PYD [56]. Moreover, educational games facilitate the acquisition of procedural knowledge and the occurrence of a higher level of cognitive process [57].
